Abstract: We introduce an intersection type system which is a restriction of the intersection type discipline. This restriction leads to a principal type property for normal forms in the classical sense, while retaining the expressivity of the classical discipline. We characterize the structure of principal types of normal forms and give an algorithm that reconstructs normal forms from types. Having shown the equivalence between principal types and normal forms, we define an expansion operation on types which allows us to recover all possible types for any normalizable λ-term. The contribution of this work is a new and simpler presentation of the intersection type discipline through a purely syntactic and completely characterized notion of principal types.

Une nouvelle présentation des systèmes de types intersections à travers le typage principal des formes normales

Résumé : Nous introduisons un système de types intersections qui est une restriction des systèmes de types intersections classiques. Cette restriction conduit à la propriété de typage principal au sens classique pour les formes normales tout en gardant l'expressivité des systèmes classiques. Nous caractérisons complètement la structure des types principaux des formes normales et nous donnons un algorithme de reconstruction d'une forme normale à partir d'un type principal. Ayant montré l'équivalence entre notre notion de type principal et les formes normales, nous définissons une opération d'expansion qui permet, composée avec l'opération de substitution, de retrouver tous les types possibles pour un λ-terme normalisable. La contribution de ce travail est la nouveauté et la simplicité de la présentation des types intersections à travers une notion de types principaux purement syntaxique et complètement caractérisée.
1 Introduction

In the approach of untyped $\lambda$-calculus as a model of programming languages, Curry’s type system is the basis of type systems of programming languages like ML [18]. Indeed, Curry’s type system has the principal type property i.e., for each typable $\lambda$-term there exists a type, the principal type, from which we can find all possible types for this term. This property is the basis of parametric polymorphism. Furthermore, the problem of typability in this system is decidable. However, this type system has some limitations: polymorphic abstractions are not allowed and types are not preserved under $\beta$-conversion. For instance, the $\lambda$-term $(\lambda x.x x)$ is not typable in this system and the $\lambda$-terms $(\lambda x.(\lambda y.y) x)$ and $(\lambda x.(\lambda y.\lambda z.x z) y) z (y z))((\lambda s.\lambda t.s)\tau)$ are $\beta$-equivalent, but they have two different principal types.

To supply a type system that does not have these drawbacks, several extensions of Curry’s type system have been proposed, the most studied of which being the intersection type discipline. Using intersection types, terms and term variables can have more than one type. This allows polymorphic abstraction, and types are invariant under $\beta$-conversion of terms [2] i.e., two $\lambda$-terms which are $\beta$-equivalent have the same type. Moreover, intersection types characterize normalizable $\lambda$-terms: a term is normalizable if and only if it is typable. Intersection type systems are therefore very expressive: this is why many authors have been interested by their theory or their usage [23, 24, 21, 10, 30].

However, the price of this expressiveness is that type assignment is only semi-decidable. Another drawback is the loss of the principal type property in the classical sense. As a matter of fact, in order to find all possible types of a term from a unique type, we must have more than just substitutions. In [6, 26, 35] a property which is similar to the principal type property is proved by adding two new operations on types: expansion and rise in [26] (or lifting in [35]). S. Ronchi della Rocca proposed a semi-algorithm for type inference in [25]. These results give important theoretical benefits, but unfortunately, they provide a good understanding neither of the structure of principal types nor of their characteristic properties. Furthermore, the semi-algorithm proposed in [25] is not practical because of its conceptual complexity. Thus, we are convinced that all interesting properties of intersection type systems have not been highlighted yet. In this paper, in order to fill this gap, we propose a new approach to intersection types. The work presented here introduces a restriction of the intersection type system presented in [1]. The type system obtained by this restriction is as expressive as the classical one [1]. Furthermore, with a restricted inference rule for variables, it gives the existence of principal types for $\lambda$-terms in normal form, in the classical sense. Further, we completely characterize the structure of these principal types and show the equivalence between normal forms and principal types. This is, to our knowledge, the first detailed study of the structural properties of principal types for intersection type systems. These properties enable us to give a simpler definition of the expansion operation than the one proposed in [6, 25, 35], and a simpler proof of the existence of a principal type for all normalizable $\lambda$-terms.

The primary motivation for this work is to tighten the theories of intersection types and $\lambda$-calculus: the coincidence of typability and normalizability lets us think that both theories can be made closer than they currently are. This work is a first step in this direction: we define a new notion of principal type, corresponding exactly to the notion of normal form in the $\lambda$-calculus. Tightening further intersection types and $\lambda$-calculus should provide a greatly simplified presentation of intersection types and therefore, a better understanding of the runtime behaviour of polymorphic programs, which itself could be used as a basis for improving the current technology of debuggers.
Normal forms

\[ N ::= x \quad \text{variable} \]
\[ \lambda x. N \quad \text{abstraction} \]
\[ x \ N_1 \ldots \ N_n \quad \text{application } n \geq 1 \]

Types

\[ \rho \in \mathcal{T} ::= \alpha \quad \text{type variable} \]
\[ [\rho_1, \ldots, \rho_n] \rightarrow \rho \quad \text{for } n \geq 0 \]

Figure 1: Normal forms and types

for polymorphic languages.

The general outline of this paper is as follows: in section 2, we introduce the type system that we study. In section 3, we characterize the sets of normalizable and head normalizable \(\lambda\)-terms through typing. Section 4 presents an inference algorithm for normal forms and proves the correctness and completeness of this algorithm with respect to the inference rules of section 2. In section 5, we state and prove the characteristic properties of principal types for normal forms. Section 6 introduces an algorithm that reconstructs normal forms from types and characterizes the set of principal types of normal forms. In section 7, we define the operation of expansion and we give some of its properties. The main result of section 8 states the principal type property for normalizable terms and section 9 gives an overview of the related works. Finally, section 10 contains a few concluding remarks.

2 Definitions

2.1 Types

In the usual definition of intersection type systems [1], there are two type constructors \(\rightarrow\) and \(\wedge\) and a type constant \(\omega\): the universal type. This type constant has been introduced to deal with the invariance under \(\beta\)-conversion for the \(\lambda K\)-terms (without \(\omega\), interesting results have been proved only for \(\lambda I\)-terms [3]).

In the first definition of intersection types introduced in [3], there is only one type constructor \(\rightarrow\). An intersection is written \([\rho_1, \ldots, \rho_n]\) and called a sequence\(^1\). Our definition of types (cf. figure 1) is close to this one. The major difference between our system and classical ones, is that we use a \(n\)-ary type constructor \([\ldots] \rightarrow \omega\) with intersections occurring on the left hand side of arrows. Therefore, in our system intersections are not types, and our syntax for types admits \([\ ] \rightarrow \rho\) as a perfectly legal type, where \([\ ]\) denotes the empty intersection.

Our set of types is clearly a restriction of the classical set of intersection types since intersections occur only on the left hand side of arrows and \(\omega\) does not belong to \(\mathcal{T}\). Nevertheless, the empty intersection allows us to type exactly all normalizable \(\lambda\)-terms. Therefore, our restriction of the set of types does not reduce the class of typable \(\lambda\)-terms.

In any case, we know that in classical intersection type systems, the notion of principal type of a term does not exist in the classical sense (see [2] for more details). In the same way, in our intersection type system, substitutions are not sufficient to deduce all possible types for a term from a unique type. For example, in our system, as in [6], we can type the term \(\lambda x.x\) (\(\lambda y.y\) with

\(^1\)Here, we prefer to call it intersection.
the type $[[\alpha] \rightarrow \alpha] \rightarrow [\beta] \rightarrow \beta$, but also with the type $[[[\alpha] \rightarrow \alpha, [\gamma] \rightarrow \gamma] \rightarrow [\beta] \rightarrow \beta$. Still there is no substitution relating the former (principal type of $(\lambda x.x \ (\lambda y.y))$ in the classical theory) to the latter.

We first study terms in normal form and we will prove that for this class of terms, the classical notion of principal type exists with a restriction of the term variable inference rule. Then we shall characterize the set of principal types.

In figure 1, we give the grammar which defines the set of normal forms and the definition of the set of types. We assume a countably infinite set $TV$ of type variables.

2.2 Occurrences and sub-terms

The notion of occurrence has been often used in literature. Different refinements have been defined (see for example [13], page 33 and 34 for positive, negative and final occurrences and [25] for level of an occurrence of a type) according to the precision of informations that the author wants to obtain with this notion. In our case, we only need to distinguish the sign of occurrences and whether or not a type variable has a final occurrence.

Definition We define the positive and negative occurrences of a type variable $\alpha$ in a type $\rho$ by induction on the structure of $\rho$ in the following way:

- if $\rho$ is a type variable, then the possible occurrence of $\alpha$ in $\rho$ is positive
- if $\rho = [\rho_1, \ldots, \rho_n] \rightarrow \rho'$, then the positive (respectively negative) occurrences of $\alpha$ in $\rho$ are the positive (respectively negative) occurrences of $\alpha$ in $\rho'$ and if $n \geq 1$, the negative occurrences of $\alpha$ in $\rho_i$ for $i = 1, \ldots, n$.

Definition Let $\rho$ be a type in $T$ and $\alpha$ a type variable. We say that $\alpha$ has a final occurrence in $\rho$ if one of the following cases is verified:

- $\rho = \alpha$
- $\rho = [\rho_1, \ldots, \rho_n] \rightarrow \rho'$ and $\alpha$ has a final occurrence in $\rho'$.

Remark: If a type variable has a final occurrence in some type then this occurrence is positive.

Afterwards, we will need to distinguish sub-terms of a type which occur in left hand side arrows.

Definition Let $\rho \in T$, the set $L(\rho)$ of left sub-terms of $\rho$ is defined by induction on the structure of $\rho$, in the following way:

- if $\rho = \alpha$, $L(\rho) = \emptyset$
- if $\rho = [\rho_1, \ldots, \rho_n] \rightarrow \rho'$, $L(\rho) = \{\rho_1, \ldots, \rho_n\} \cup L(\rho')$.

We also define a mapping $TypeVar$ from types to sets of type variables. This function returns the set of type variables which occur in a type.
2.3 Substitutions

The operation of substitution is defined as usual: a substitution is a mapping from type variables to types, which can be extended in a natural way to a mapping from types to types. The domain of a substitution $S$ is the set of type variables which are modified by $S$. More formally:

$$\text{Dom}(S) = \{ \alpha \in TV | S(\alpha) \neq \alpha \}$$

We write $[\alpha/\rho]$ the substitution that maps $\alpha$ to $\rho$ and leaves other type variables unchanged.

We define the substitution $S_1 + S_2$ where the two substitutions $S_1$ and $S_2$ have disjoint domains in the following way:

$$(S_1 + S_2)(\alpha) = \begin{cases} 
S_i(\alpha) & \text{if } \alpha \in \text{Dom}(S_i), i = 1 \text{ or } 2 \\
\alpha & \text{if } \alpha \notin \text{Dom}(S_1) \cup \text{Dom}(S_2)
\end{cases}$$

2.4 Constraint environments

We can now define constraint environments and their associated operations. This notion of constraint environment was introduced by Z. Shao and A. Appel in [29] where it was called assumption environment. Informally, a constraint environment links the free term variables of a $\lambda$-term with their type constraints. Since we study the principal type property of $\lambda$-terms, we prefer this notion of constraint environment to the notion of basis used in all papers about intersection type discipline. Bases give some hypothesis about the types of free term variables. Using constraint environments leads us to obtain the minimal type constraints for free term variables. S. van Bakel in [35], must distinguish between basis, used basis, and minimal basis. Since we are only interested in the equivalent of van Bakel’s minimal basis, it is enough to have one definition.

Definition A constraint environment $A$, is a mapping from the set $V$ of term variables to the multi-sets of types. We use multi-sets rather than simple sets to keep track of the different occurrences of the same type.

The empty multi-set is written $[]$ and the multi-set of types $\rho_1, \ldots, \rho_n$ is written $[\rho_1, \ldots, \rho_n]$. These notations allow us to write the type $A(x) \rightarrow \rho$ for any constraint environment $A$, any term variable $x$ and any type $\rho$, consistently with the syntax of types.

In order to handle easily these constraint environments, we introduce several operations giving informations on constraint environments or transforming them.

Definition Let $A$ be a constraint environment. We define the domain of $A$, written $\text{Dom}(A)$ as:

$$\text{Dom}(A) = \{ x \in V | A(x) \neq [] \}$$

Let $A$ be a constraint environment such that $\text{Dom}(A) = \{x_1, \ldots, x_n\}$ and $A(x_i) = [\rho_{i1}, \ldots, \rho_{ip_i}]$, for all $i \in \{1, \ldots, n\}$. We use the following notation for $A$:

$$\{x_1 : [\rho_{i1}, \ldots, \rho_{ip_1}], \ldots, x_n : [\rho_{n1}, \ldots, \rho_{np_n}]\}$$

The two following operations allow, respectively, to restrict and extend the domain of a constraint environment.
\[
\begin{align*}
\Gamma \vdash \varphi; \{x : [\rho]\} & \quad \text{(VAR)} \\
\Gamma \vdash \varphi_1; \rho_1; A_1 & \quad \rightarrow \quad \Gamma \vdash \lambda x. \varphi_1 : A_1(x) \rightarrow \rho_1; A_1 \setminus \{x\} & \quad \text{(ABS)} \\
\Gamma \vdash \varphi_1 : [\rho_1^1, \ldots, \rho_1^n] \rightarrow \rho_1; A_1 & \quad \rightarrow \quad \Gamma \vdash \varphi_2 : [\rho_2^1, \rho_2^1, \ldots, \rho_2^n] A_2 & \quad \rightarrow \quad \Gamma \vdash \varphi_2 : [\rho_2^n, \rho_2^n, \ldots, \rho_2^n] A_2 & \quad (n \geq 0) & \quad \text{APP} \\
\Gamma \vdash \varphi_1 \varphi_2 : [\rho_1^1, \ldots, \rho_1^n] \rightarrow \rho_1; A_1 + A_2^1 + \ldots + A_2^n & \quad \rightarrow \quad \Gamma \vdash \varphi_2 : [\rho_2^1, \rho_2^1, \ldots, \rho_2^n] A_2 & \quad \rightarrow \quad \Gamma \vdash \varphi_2 : [\rho_2^n, \rho_2^n, \ldots, \rho_2^n] A_2 & \quad (n \geq 0) & \quad \text{APP}
\end{align*}
\]

Figure 2: Inference rules

**Definition** Let \( A \) be a constraint environment and \( x \) be a term variable, we define the constraint environment \( A \setminus \{x\} \) by:

\[
A \setminus \{x\}(y) = \begin{cases} A(y) & \text{if } y \neq x \\ [] & \text{otherwise} \end{cases}
\]

**Definition** Let \( A_1 \) and \( A_2 \) be two constraint environments, the constraint environment \( A_1 + A_2 \) is defined as:

\[
(A_1 + A_2)(x) = A_1(x) \cup A_2(x), \text{ for all } x \in V
\]

where \( \cup \) is the union of multi-sets.

**Remark:** We adopt the usual conventions for omitting parentheses in types and terms and some other syntactic conventions: we use metavariables \( x, y, \ldots \) to denote term variables, \( \alpha, \beta, \gamma, \ldots \) for type variables, and \( A, A_1, \ldots \) for constraint environments.

### 2.5 Type assignments

The type assignment relations \( \vdash_{sw} \) and \( \vdash_{sw,p} \), relating \( \lambda \)-terms, types, and constraint environments, are defined in figure 2.

In fact, \( \vdash_{sw,p} \) is a restriction of the type assignment \( \vdash_{sw} \) since the only difference between \( \vdash_{sw,p} \) and \( \vdash_{sw} \) is in the typing rules for variables: while the typing rule for variables (VAR) allows us to type a term variable without restriction on its structure, our (VARp) rule gives a strong restriction on the structure of the type which occurs in that rule. We shall see in the following section, that this restriction enables us to find all types of normal forms using just substitutions. We also notice
that in the rules for applications, if \( n = 0 \) then there is only one premise in that inference rule and the argument of the application does not interfere in the derivation.

### 3 Expressiveness of type system

In this section, we are only interested in the type assignment \( \vdash_{\text{sw}} \). We prove that though we have restricted the set of types in our system, we can characterize normalizable \( \lambda \)-terms and head normalizable \( \lambda \)-terms according to the structure of the assigned type as we can do in the classical intersection type systems. A number of proofs of these results for intersection type discipline have been written, the first one can be found in [1] and we follow the method of [13].

First, we show that two \( \beta \)-equivalent \( \lambda \)-terms have the same type and the same constraint environment. Then we prove that every term in normal form or in head normal form is typable. Finally, we give a translation from our type system to the classical intersection type system which enable us to use the normalization theorems proved for this system [1, 13].

#### 3.1 Stability under \( \beta \)-conversion

To prove this property, we show independently the stability under \( \beta \)-expansion and under \( \beta \)-reduction.

##### 3.1.1 \( \beta \)-expansion

The following lemma and its proof are technical, but they explain how the typing derivation of a term \( e[x/f] \) is transformed to obtain a typing derivation of \( e \).

**Lemma 1** Let \( x \) be a term variable, \( e \) and \( f \) two \( \lambda \)-terms such that \( x \) has at least one free occurrence in \( e \). If \( \vdash_{\text{sw}} e[x/f] : \rho; A \) then there exist an interger \( n \geq 1 \), \( n \) types: \( \rho_1, \ldots, \rho_n \) and \( n \) constraint environments: \( A_1, \ldots, A_n \), such that:

- \( \forall i \in \{1, \ldots, n\}, \vdash_{\text{sw}} f : \rho_i; A_i \)
- \( A = A' + A_1 + \cdots + A_n \) for one \( A' \) such that \( A'(x) = [] \)
- \( \vdash_{\text{sw}} e : \rho; A' + \{x : [\rho_1, \ldots, \rho_n]\} \)

**Proof** by recurrence on the length of the typing derivation of \( e \).

- If \( e = x \) then \( e[x/f] = f \) and we have the derivation \( \vdash_{\text{sw}} f : \rho; A \), since by hypothesis \( \vdash_{\text{sw}} e[x/f] : \rho; A \). Moreover, according to the inference rule (VAR), we have \( \vdash_{\text{sw}} x : \rho; \{x : [\rho]\} \). Thus, the type \( \rho \) and the constraint environment \( A \) are such that:
  
  - \( \vdash_{\text{sw}} f : \rho; A \)
  - \( A = A' + A \) with \( A' = \{\} \) and \( A'(x) = [] \)
  - \( \vdash_{\text{sw}} e : \rho; \{\} + \{x : [\rho]\} \)

6
• If \( e = \lambda y. e_c \) then \( e[x/f] = \lambda y. e_c[x/f] \) and we have:

\[
\Gamma \vdash^{\text{sw}} e_c[x/f] : \rho_c; A_c
\]

\[
\Gamma \vdash^{\text{sw}} \lambda y. e_c[x/f] : A_c(y) \rightarrow \rho_c; A_c \setminus \{y\}
\]

with \( \rho = A_c(y) \rightarrow \rho_c \) and \( A = A_c \setminus \{y\} \).

Since \( x \) has at least one free occurrence in \( e \), \( x \) has at least one free occurrence in \( e_c \) and we have \( y \neq x \). So by the recurrence hypothesis on the typing derivation of \( e_c \), there exist \( n \) types \( \rho_1, \ldots, \rho_n \) and \( n \) constraint environments \( A_1, \ldots, A_n \) such that:

- \( \forall i \in \{1, \ldots, n\}, \Gamma \vdash^{\text{sw}} f : \rho_i; A_i \)
- \( A_c = A'_c + A_1 + \cdots + A_n \) for one \( A'_c \) such that \( A'_c(x) = [] \)
- \( \Gamma \vdash^{\text{sw}} e_c : \rho_c; A'_c + \{x : [\rho_1, \ldots, \rho_n]\} \)

By the inference rule (VAR), \( \Gamma \vdash^{\text{sw}} \lambda y. e_c : A'_c(y) \rightarrow \rho_c; A'_c \setminus \{y\} + \{x : [\rho_1, \ldots, \rho_n]\} \)

We must show that:

- \( \forall i \in \{1, \ldots, n\}, \Gamma \vdash^{\text{sw}} f : \rho_i; A_i \)
- \( A = A'_c + A_1 + \cdots + A_n \) with \( A'_c = A'_c \setminus \{y\} \) and \( (A'_c \setminus \{y\})(x) = [] \)
- \( \Gamma \vdash^{\text{sw}} \lambda y. e_c : \rho_c; A'_c + \{x : [\rho_1, \ldots, \rho_n]\} \).

The first case is exactly the recurrence hypothesis given previously.

For the second case, since \( A = A_c \setminus \{y\} \) and \( A_c = A'_c + A_1 + \cdots + A_n \), we must show that \( A_c \setminus \{y\} = A'_c \setminus \{y\} + A_1 + \cdots + A_n \) i.e., \( A_i \setminus \{y\} = A_i \). But, we can suppose without loss of generality, that \( y \) has no free occurrence in \( f \) since by definition of the substitution of a variable in a \( \lambda \)-term, the free variables of \( f \) are always free in \( e[x/f] \). Thus the free occurrences of \( y \) in \( e_c \) are the same as in \( e_c[x/f] \) and for all \( i \in \{1, \ldots, n\}, A_i(y) = [] \). So \( A = A'_c \setminus \{y\} + A_1 + \cdots + A_n \). We still have to show that \( (A'_c \setminus \{y\})(x) = [], \) but it is clear since \( (A'_c \setminus \{y\})(x) \subset A'_c(x) = [] \).

For the last case, we have \( \Gamma \vdash^{\text{sw}} \lambda y. e_c : A'_c(y) \rightarrow \rho_c; A'_c \setminus \{y\} + \{x : [\rho_1, \ldots, \rho_n]\} \). Since \( \rho = A_c(y) \rightarrow \rho_c \), we must show that \( A_c(y) = A'_c(y) \). But we have seen that for all \( i \in \{1, \ldots, n\}, A_i(y) = [] \) and thus \( A_c(y) = A'_c(y) + A_1(y) + \cdots + A_n(y) = A'_c(y) \).

• If \( e = e_f e_a \) then \( e[x/f] = e_f[x/f] e_a[x/f] \) and we have derived:

\[
\Gamma \vdash^{\text{sw}} e_f[x/f] : [\rho^f_0, \ldots, \rho^f_{P_f}] \rightarrow \rho; A_f
\]

\[
\Gamma \vdash^{\text{sw}} e_a[x/f] : [\rho^a_0, A^a_1, \ldots, \rho^a_{P_a}, A^a_{P_a}]
\]

\[
\Gamma \vdash^{\text{sw}} (e_f e_a)[x/f] : [\rho^f_0, \rho^a_0; A^a_1, \ldots, \rho^a_{P_a}; A^a_{P_a}]
\]

with \( A = A_f + A^a_1 + \cdots + A^a_{P_a} \).

Several cases arise according to the repartition of the free occurrences of \( x \) in \( e_f e_a \):

○ Let suppose that \( x \) has at least one free occurrence in \( e_f \) and \( e_a \).

By the recurrence hypothesis on the typing derivation of \( e_f \), there exist \( n \) types \( \rho_1, \ldots, \rho_n \) and \( n \) constraint environments \( A_1, \ldots, A_n \) such that:
In the same way, we can apply the recurrence hypothesis to each typing derivation \( \vdash_{s\omega} \ e_a : \rho^1; A^1_i \). Thus for all \( i \in \{1, \ldots, p\} \), there exist \( n_i \) types \( \rho^1_1, \ldots, \rho^1_{n_i} \) and \( n_i \) constraint environments \( A^1_1, \ldots, A^1_{n_i} \) such that:

\[
\forall j \in \{1, \ldots, n_i\}, \vdash_{s\omega} \ f : \rho^1_j; A^1_j
\]

\[
A^i_1 = B^1_2 + A^1_1 + \cdots + A^1_{n_i} \text{ for one } B^1_2 \text{ such that } B^1_2(x) = []
\]

\[
\vdash_{s\omega} \ e_a : \rho^1_1; B^1_2 + \{ x : [\rho^1_1, \ldots, \rho^1_{n_i}] \}
\]

We deduce the following derivation:

\[
\vdash_{s\omega} \ e_f : [\rho^1_0, \ldots, \rho^p_0] \rightarrow \rho; A_f + \{ x : [\rho^1, \ldots, \rho_n] \}
\]

\[
\vdash_{s\omega} \ e_a : \rho^1_0; B^1_2 + \{ x : [\rho^1_1, \ldots, \rho^1_1] \}
\]

\[
\vdash_{s\omega} \ e_a : \rho^p_0; B^p_2 + \{ x : [\rho^p_1, \ldots, \rho^p_{n_p}] \}
\]

\[
\vdash_{s\omega} \ e_f \quad e_a : \rho; A_f^i + B^1_2 + \cdots + B^p_2 + \{ x : [\rho^1, \ldots, \rho_n, \rho^1_1, \ldots, \rho^1_{n_1}, \ldots, \rho^p_1, \ldots, \rho^p_{n_p}] \}
\]

Since \( A_f^i(x) = [] \) and \( B^i_2(x) = [] \) for all \( i \in \{1, \ldots, p\} \), \((A_f^i + B^1_2 + \cdots + B^p_2)(x) = []\)

Moreover, we have \( A = A_f + A^1_1 + \cdots + A^1_{n_1}, A_f = A_f^1 + A^1_1 + \cdots + A^1_{n_1}, \text{ and for all } i \in \{1, \ldots, p\}, \)

\[
A^i_1 = B^i_2 + A^1_1 + \cdots + A^1_{n_i},
\]

so

\[
A = A_f^1 + A^1_1 + \cdots + A^1_{n_1} + B^1_2 + \cdots + B^p_2 + A^1_1 + \cdots + A^1_{n_1} + \cdots + A^1_{n_p} + \cdots + A^p_{n_p}
\]

Let \( N = n + n_1 + \cdots + n_p \).

The \( N \) types: \( \rho_1, \ldots, \rho_n, \rho^1_1, \ldots, \rho^1_{n_1}, \ldots, \rho^p_1, \ldots, \rho^p_{n_p} \), and the \( N \) constraint environments: \( A_1, \ldots, A_n, A^1_1, \ldots, A^1_{n_1}, \ldots, A^1_{n_p}, \ldots, A^p_{n_p} \), are such that:

\[
\vdash_{s\omega} \ f : \rho_j; A_j \text{ for } j = 1, \ldots, n \text{ and } \vdash_{s\omega} \ f : \rho^j_i; A^j_i \text{ for } i = 1, \ldots, p \text{ and } j = 1, \ldots, n_i
\]

\[
A = A_f^1 + B^1_2 + \cdots + B^p_2 + A^1_1 + \cdots + A^1_{n_1} + \cdots + A^1_{n_p} + \cdots + A_{n_i}
\]

\[
(\vdash_{s\omega} \ e_f : [\rho^1_0, \rho^p_0]) \rightarrow \rho; A_f^i
\]

\[
\vdash_{s\omega} \ e : \rho; A_f^i + B^1_2 + \cdots + B^p_2 + \{ x : [\rho^1, \ldots, \rho_n, \rho^1_1, \ldots, \rho^1_{n_1}, \ldots, \rho^p_1, \ldots, \rho^p_{n_p}] \}
\]

\(\circ\) Let suppose that \( x \) has no free occurrence in \( e_f \), then \( x \) has at least one free occurrence in \( e_a \). Like in the previous case we can apply the recurrence hypothesis to each typing derivation of \( e_a \). We notice that if \( x \) has no free occurrence in \( e_f \) then \( e_f[x/f] = e_f \) and

\[
\vdash_{s\omega} \ e_f : [\rho^1_0, \rho^p_0] \rightarrow \rho; A_f
\]

The result can be deduced from the recurrence hypothesis and from the equality \( A_f(x) = [] \).

\(\circ\) The last case where \( x \) has no free occurrence in \( e_a \) is similar to the previous case. It is enough to apply the recurrence hypothesis to \( e_f \) and notice that \( e_a[x/f] = e_a \) and \( A^i_a(x) = [] \), for all \( i = 1, \ldots, p \).
Now, we prove that a redex has the same type and the same constraint environment as the corresponding \( \beta \)-reduced term.

**Lemma 2** Let \( x \) a term variable, \( e \) and \( f \) two \( \lambda \)-terms. If \( \vdash_{sw} e[x/f] : \rho; A \) then \( \vdash_{sw} (\lambda x.e) f : \rho; A \).

**Proof** by case on the number of occurrences of \( x \) in \( e \).

- If \( x \) has no free occurrence in \( e \) then \( e[x/f] = e \) and by hypothesis, \( \vdash_{sw} e : \rho; A \). Since in our type system the domain of the constraint environment \( A \) only holds the free variables of \( e \), we have \( A(x) = [] \) and the following derivation:

\[
\begin{align*}
\vdash_{sw} e & : \rho; A \\
\vdash_{sw} \lambda x.e : [] & \rightarrow \rho; A \\
\vdash_{sw} (\lambda x.e)f & : \rho; A
\end{align*}
\]

It proves that \( (\lambda x.e)f \) has the same type and the same constraint environment as \( e[x/f] \).

- Otherwise \( x \) has at least one free occurrence in \( e \). By hypothesis, \( \vdash_{sw} e[x/f] : \rho; A \). So by the lemma 1, there exist \( n \) types: \( \rho_1, \ldots, \rho_n \) and \( n \) constraint environments: \( A_1, \ldots, A_n \), such that:

\[
\begin{align*}
- \forall i \in \{1, \ldots, n\}, \vdash_{sw} f & : \rho_i; A_i \\
- A & = A' + A_1 + \cdots + A_n \text{ for one } A' \text{ such that } A'(x) = [] \\
- \vdash_{sw} e & : \rho; A' + \{x : [\rho_1, \ldots, \rho_n]\}
\end{align*}
\]

But \( (A' + \{x : [\rho_1, \ldots, \rho_n]\})(x) = [\rho_1, \ldots, \rho_n] \) and \( (A' + \{x : [\rho_1, \ldots, \rho_n]\}) \setminus \{x\} = A' \) since \( A'(x) = [] \). We deduce the following derivation:

\[
\begin{align*}
\vdash_{sw} e & : \rho; A' + \{x : [\rho_1, \ldots, \rho_n]\} \\
\vdash_{sw} \lambda x.e : [\rho_1, \ldots, \rho_n] & \rightarrow \rho; A' \\
\vdash_{sw} f & : \rho_1; A_1 \quad \vdots \quad \vdash_{sw} f & : \rho_n; A_n \\
\vdash_{sw} (\lambda x.e)f & : \rho; A' + A_1 + \cdots + A_n
\end{align*}
\]

Thus \( (\lambda x.e)f \) and \( e[x/f] \) has the same type and the same constraint environment. \( \square \)

The previous lemma states a result for a redex and its contraction, we generalize this result for two \( \beta \)-equivalent terms in the following theorem.

**Theorem 1** Let \( e \) and \( e' \) two \( \lambda \)-terms such that \( e \) can be \( \beta \)-reduced in \( e' \). If \( \vdash_{sw} e' : \rho; A \) then \( \vdash_{sw} e : \rho; A \).

**Proof** by structural induction on \( e, e'/ \). We can suppose, without lost of generality, that \( e' \) differs of \( e \) only by the contraction of one redex.

- If \( e = x \) then this case is impossible since we can not \( \beta \)-reduce \( e \) in \( e' \).

- If \( e = \lambda x.e_1 \) then \( e' = \lambda x.e_1' \) with \( e_1 \) which is reduced, by the contraction of one redex, in \( e_1' \). Thus if we have:

\[
\begin{align*}
\vdash_{sw} e_1 & : \rho'; A' \\
\vdash_{sw} \lambda x.e_1' : A'(x) & \rightarrow \rho'; A' \setminus \{x\}
\end{align*}
\]
with \( \rho = A'(x) \rightarrow \rho' \) and \( A = A' \setminus \{ x \} \) then by the induction hypothesis we have \( \vdash_{sw} e_1 : \rho' ; A' \). So by the inference rule for abstraction, we have \( \vdash_{sw} \lambda x.e_1 : \rho ; A \).

- If \( e = e_1 e_2 \) then three cases are possible:

  - \( e' = e_1' e_2 \) with \( e_1 \) which is reduced to \( e_1' \) by the contraction of one redex and we have:
    \[
    \vdash_{sw} e_1' : [\rho_2^1, \ldots, \rho_2^n] \rightarrow \rho ; A_1 \quad \vdash_{sw} e_2 : \rho_1^0 ; A_2^n
    \]
    \[
    \vdash_{sw} e_1' e_2 : \rho ; A_1 + A_2^1 + \cdots + A_2^n
    \]
    with \( A = A_1 + A_2^1 + \cdots + A_2^n \).
    Then by induction, \( \vdash_{sw} e_1 : [\rho_2^1, \ldots, \rho_2^n] \rightarrow \rho ; A_1 \), and by application of the inference rule (APP), \( \vdash_{sw} e_1 e_2 : \rho ; A \).

  - or \( e' = e_1 e_2' \) with \( e_2 \) which is reduced to \( e_2' \) and we have:
    \[
    \vdash_{sw} e_1 : [\rho_2^1, \ldots, \rho_2^n] \rightarrow \rho ; A_1 \quad \vdash_{sw} e_2' : \rho_1^1 \rightarrow A_2^1 \quad \vdash_{sw} e_2' : \rho_1^2 ; A_2^1 \ldots \vdash_{sw} e_2' : \rho_1^n ; A_2^n
    \]
    \[
    \vdash_{sw} e_1 e_2' : \rho ; A_1 + A_2^1 + \cdots + A_2^n
    \]
    with \( A = A_1 + A_2^1 + \cdots + A_2^n \).
    Then by induction, for each derivation \( \vdash_{sw} e_2' : \rho_1^i ; A_2^i \), we have \( \vdash_{sw} e_2 : \rho_1^i ; A_2^i \) and by the inference rule (APP) \( \vdash_{sw} e_1 e_2 : \rho ; A \).

  - otherwise \( e_1 = \lambda x.f \) and \( e' = f[x/e_2] \) with \( \vdash_{sw} e' : \rho ; A \). By the lemma 2, \( \vdash_{sw} (\lambda x.f)e_2 : \rho ; A \).

\( \square \)

### 3.1.2 \( \beta \)-reduction

To prove the stability under \( \beta \)-reduction, we follow the same method as for \( \beta \)-expansion. We show successively how the typing derivation of a term \( e \) is transformed to obtain a typing derivation of \( e[x/f] \), that the typing assignments of a redex and its contraction are the same, and that the typing assignments of two \( \beta \)-equivalent terms are the same.

**Lemma 3** Let \( x \) be a term variable, \( e \) and \( f \) \( \lambda \)-terms such that \( x \) has at least one free occurrence in \( e \). If \( \vdash_{sw} e : \rho ; A \{ x : [\rho_1, \ldots, \rho_n] \} \) and \( \vdash_{sw} f : \rho_i ; A_i \) for \( i = 1, \ldots, n \) then \( \vdash_{sw} e[x/f] : \rho ; A + A_1 + \cdots + A_n \).

**Proof** by structural induction on \( e \).

- If \( e = x \) then \( e[x/f] = f \) and \( \vdash_{sw} x : \rho ; \{ x : [\rho] \} \) with \( A = [\] \). Since by hypothesis, \( \vdash_{sw} f : \rho ; A' \) for one \( A' \), we have \( \vdash_{sw} e[x/f] : \rho ; A + A' \).

- If \( e = \lambda y.e_1 \) then \( e[x/f] = \lambda y.e_1[x/f] \) and we have:
  \[
  \vdash_{sw} e_1 : \rho' ; A + \{ y : [\rho_1, \ldots, \rho_m] \} + \{ x : [\rho_1, \ldots, \rho_n] \}
  \]
  \[
  \vdash_{sw} \lambda y.e_1 : [\rho_1, \ldots, \rho_m] \rightarrow \rho' ; A + \{ x : [\rho_1, \ldots, \rho_n] \}
  \]
with \( \rho = [\rho_1, \ldots, \rho_n] \rightarrow \rho' \).

Moreover \( x \) and \( y \) are distinct variables since \( x \) has at least one free occurrence in \( e \). We can suppose, without loss of generality, that \( y \) has no free occurrence in \( f \). So by the induction hypothesis, \( \vdash_{\sw} e_1[x/f] : \rho' \cdot A + \{ y : [\rho_1, \ldots, \rho_n] \} + A_1 + \cdots + A_n \) and from the inference rule (\text{ABS}) we deduce that \( \vdash_{\sw} \lambda y. e_1[x/f] : \rho' \cdot A + A_1 + \cdots + A_n \).

- If \( e = e_1 e_2 \) then as in the lemma 1, we must distinguish several cases according to the repartition of free occurrences of \( x \) in \( e_1 \) and \( e_2 \). In the three cases, it is enough to use the induction hypothesis and the inference rule (\text{APP}) to show that \( \vdash_{\sw} e_1 e_2[x/f] : \rho' \cdot A + A_1 + \cdots + A_n \).

**Lemma 4** Let \( x \) be a term variable, \( e \) and \( f \) two \( \lambda \)-terms. If \( \vdash_{\sw} (\lambda x.e) f : \rho ; A \) then \( \vdash_{\sw} e[x/f] : \rho ; A \).

**Proof**

- If \( x \) has no free occurrence in \( e \) then \( e[x/f] = e \) and we have the following derivation:

\[
\begin{align*}
\vdash_{\sw} e : \rho ; A & \quad A(x) = [] \\
\vdash_{\sw} \lambda x.e : [] & \rightarrow \rho ; A \\
\vdash_{\sw} (\lambda x.e)f : \rho ; A
\end{align*}
\]

Thus we have \( \vdash_{\sw} e[x/f] : \rho ; A \).

- Otherwise \( x \) has at least one free occurrence in \( e \). Since we have supposed that \( \vdash_{\sw} (\lambda x.e) f : \rho ; A \), we have the following derivation:

\[
\begin{align*}
\vdash_{\sw} e : \rho ; A' & \quad A'(x) = [\rho_1, \ldots, \rho_n] \\
\vdash_{\sw} \lambda x.e : [\rho_1, \ldots, \rho_n] & \rightarrow \rho ; A' \setminus \{ x \} \\
\vdash_{\sw} f : \rho ; A_i
\end{align*}
\]

with \( A = A' \setminus \{ x \} + A_1 + \cdots + A_n \).

According to the lemma 3, we have \( \vdash_{\sw} e[x/f] : \rho ; A' \setminus \{ x \} + A_1 + \cdots + A_n \).

**Theorem 2** Let \( e \) and \( e' \) be two \( \lambda \)-terms such that \( e' \) is obtained by \( \beta \)-reduction from \( e \). If \( \vdash_{\sw} e : \rho ; A \) then \( \vdash_{\sw} e' : \rho ; A \).

**Proof** by structural induction on \( e \).

We can suppose that \( e \) and \( e' \) only differs in the contraction of one redex.

- If \( e = x \) then this case is impossible since \( e \) can not be reduced in \( e' \).

- If \( e = \lambda x.e_1 \) then \( e' = \lambda x.e'_1 \) where \( e'_1 \) is obtained from \( e_1 \) by \( \beta \)-reduction and we have derived:

\[
\begin{align*}
\vdash_{\sw} e_1 : \rho_1 ; A_1 \\
\vdash_{\sw} \lambda x.e_1 : A_1 \rightarrow \rho_1 ; A_1 \setminus \{ x \}
\end{align*}
\]

with \( \rho = A_1(x) \rightarrow \rho_1 \) et \( A = A_1 \setminus \{ x \} \). Thus by the induction hypothesis we have \( \vdash_{\sw} e'_1 : \rho_1 ; A_1 \).

We deduce \( \vdash_{\sw} \lambda x.e'_1 : \rho ; A \).

- If \( e = e_1 e_2 \) then as for the theorem 1 three cases are possible:
\( e' = e_1 e_2 \) or \( e' = e'_1 e_2 \) then we use the induction hypothesis and the inference rule (APP).

\( e' = (\lambda x.f)e_2 \) then \( e' = f[x/e_2] \) and we use the previous lemma.

\( \square \)

### 3.1.3 \( \beta \)-conversion

**Theorem 3** If \( e = \beta e' \) then \( \vdash_{\text{\( \omega \)}} e : \rho; A \) if and only if \( \vdash_{\text{\( \omega \)}} e' : \rho; A \).

**Proof** by the theorems 1 and 2. \( \square \)

### 3.2 Characterization of normalizable \( \lambda \)-terms

To prove the normalization theorem and the head normalization theorem, we use the corresponding results proved for the classical intersection type system. But we do not recall the definitions of the set of types and of the typing assignment in this system. The reader can see [2] for more details.

#### 3.2.1 Translation between \( T \) and \( T_{\land \omega} \)

The sets of types in our type system and in the classical intersection type system do not use the same syntax, so to make the link between the both type systems, we need to define a translation function which defines a type of \( T_{\land \omega} \) for all type of \( T \).

**Definition** We define a function \( (\_ )_{\land \omega} \) translating a type \( \rho \) of \( T \) in a type \( (\rho)_{\land \omega} \) of \( T_{\land \omega} \) defined by induction on the structure of \( \rho \):

- if \( \rho = \alpha \) then \( (\rho)_{\land \omega} = \alpha \)
- if \( \rho = [\ ] \rightarrow \rho' \) then \( (\rho)_{\land \omega} = \omega \rightarrow (\rho)_{\land \omega} \)
- if \( \rho = [\rho_1, \ldots, \rho_n] \rightarrow \rho' \) with \( n \neq 0 \) then \( (\rho)_{\land \omega} = (\rho_1)_{\land \omega} \land \ldots \land (\rho_n)_{\land \omega} \rightarrow (\rho')_{\land \omega} \)

This function is an injection but not a bijection: there exist no type \( \rho \) of \( T \) such that \( (\rho)_{\land \omega} = \omega \).

We extend this translation to constraint environments in the following way:

- if \( a \neq \{ \} \) then \( (A)_{\land \omega} = \emptyset \)
- if \( A = \{ x : [\rho] \} \) then \( (A)_{\land \omega} = \{ x : (\rho)_{\land \omega} \} \)
- if \( A = A_1 + A_2 \) then \( (A)_{\land \omega} = (A_1)_{\land \omega} + (A_2)_{\land \omega} \)

where \( + \) is the union of two bases such that if \( x : \tau_1 \in (A_1)_{\land \omega} \) and if \( x : \tau_2 \in (A_2)_{\land \omega} \) then \( x : \tau_1 \land \tau_2 \in (A_1)_{\land \omega} + (A_2)_{\land \omega} \).

**Theorem 4** Let \( e \) be a \( \lambda \)-term. If \( \vdash_{\text{\( \omega \)}} e : \rho; A \) then \( e \vdash_{\land \omega} (\rho)_{\land \omega} : (A)_{\land \omega} \).

**Proof** by structural induction on \( e \). \( \square \)
3.2.2 Normalizable λ-terms

The characterization of normalizable λ-terms depends on the structure of assigned types. Thus an important notion is the notion of proper types. Before defining this notion, we need to give the definition of the level of an occurrence in a type.

**Definition** We define the level of an occurrence of [] in a type ρ by induction on the structure of ρ:

- if ρ = [] → ρ′ then the level of [] in ρ is 1
- if ρ = [ρ₁, ..., ρₙ] → ρ′ then the level of an occurrence of [] in ρ is the level of the corresponding occurrence of [] in ρ′ or the level of the corresponding occurrence of [] in one of the ρᵢ +1.

**Definition** We say that ρ is a proper type if [] has no occurrence in ρ or if [] has only occurrences at odd levels.

We can extend this definition to constraint environments. A constraint environment A is a proper constraint environment if [] has no occurrence in A or if [] only occurs in a type of A at even levels.

**Lemma 5** Let ρ be a proper type and A a proper constraint environment. Their translation in $\mathcal{T}_{\omega \wedge}$, $(\rho)_{\omega \wedge}$ and $(A)_{\omega \wedge}$ are respectively a proper type and a proper basis.

**Proof**

It is enough to notice that the translation does not change the structure of types and that each occurrence of [] becomes an occurrence of ω. Thus the levels of occurrences of ω in $(\rho)_{\omega \wedge}$ and $(A)_{\omega \wedge}$ are the one of [] in ρ and A, so they have the same parity.□

**Theorem 5** Let $e$ be a normalizable λ-term such that $\vdash_{\omega \wedge} e : \rho; A$ where ρ and A are proper. Then e is normalizable.

**Proof**

According to the theorem 4, we have $(A)_{\omega \wedge} \vdash_{\omega} e : (\rho)_{\omega \wedge}$ and by the lemma 5, $(A)_{\omega \wedge}$ and $(\rho)_{\omega \wedge}$ are respectively a proper basis and a proper type. By the normalization theorem of the system $\mathcal{D}_\omega$ (cf. [7]), e is normalizable.□

**Lemma 6** Let $e$ be a λ-term in normal form. There exist a proper type ρ and a proper constraint environment A such that $\vdash_{\omega \wedge} e : \rho; A$.

**Proof** by induction on the structure of a normal form.

- If $e = x$ then let ρ be a type which has no occurrence of []. We can derive $\vdash_{\omega \wedge} x : \rho; A$ with $A = \{ x : [\rho] \}$. Since [] has no occurrence neither in ρ nor in A, they are both proper.
- If $e = \lambda x . e_1$ where $e_1$ is in normal form then by the induction hypothesis, there exist $A_1$ and $\rho_1$ proper such that $\vdash_{\omega \wedge} e_1 : \rho_1; A_1$. Thus there exist $A = A_1 \setminus \{ x \}$ and $\rho = A_1(x) → \rho_1$ such that $\vdash_{\omega \wedge} e : \rho; A$.

We must prove that ρ and A are proper. The occurrences of [] in $A_1(x)$ are at even level since $A_1$ is proper. This occurrences are at odd level in $A_1(x) → \rho_1$. Moreover the level of the occurrences of [] in $\rho_1$ do not change in $A_1(x) → \rho_1$. Thus $A_1(x) → \rho_1$ and $A_1 \setminus \{ x \}$ are proper.

- If $e = x^1 e_1 \ldots e_n$ where for all $i \in \{ 1, \ldots, n \}$, $e_i$ is in normal form, then by the induction hypothesis, for each $e_i$ there exist proper $A_i$ and $\rho_i$ such that $\vdash_{\omega \wedge} e_i : \rho_i; A_i$. We have
\( \vdash_{\text{sw}} x_1 \ldots x_n : \alpha; \{ x : [\rho_1] \to \cdots \to [\rho_n] \to \alpha \} + A_1 + \cdots + A_n \) where \( \alpha \) is a type variable. The occurrences of \([\cdot] \) in \( \rho_i \) are at odd level since \( \rho_i \) is proper. These occurrences are at even level in \([\rho_1] \to \cdots \to [\rho_n] \to \alpha \). Thus \( \{ x : [\rho_1] \to \cdots \to [\rho_n] \to \alpha \} + A_1 + \cdots + A_n \) is proper. □

**Theorem 6** Let \( e \) be a normalizable \( \lambda \)-term. There exist a proper type \( \rho \) and a proper constraint environment \( A \) such that \( \vdash_{\text{sw}} e : \rho; A \).

**Proof** Since \( e \) is a normalizable \( \lambda \)-term, there exists a \( \lambda \)-term \( e' \) in normal form such that \( e =_\beta e' \). By the lemma 6, there exist a proper constraint environment \( A \) and a proper type \( \rho \) such that \( \vdash_{\text{sw}} e' : \rho; A \). And by the theorem 3, we have \( \vdash_{\text{sw}} e : \rho; A \). □

**Corollary** A \( \lambda \)-term is normalizable if and only if it is typable with a proper type and a proper constraint environment.

**Proof** by the theorems 5 and 6. □

### 3.2.3 Head normalizable \( \lambda \)-terms

**Theorem 7** Let \( e \) be a \( \lambda \)-term such that \( \vdash_{\text{sw}} e : \rho; A \). Then \( e \) has a head normal form.

**Proof** By the theorem 4, every term typable in our system is typable in \( D_\omega \) by a type distinct of \( \omega \) since \([\cdot] \) is not a type. But in \( D_\omega \), every term typable with a type distinct of \( \omega \) has a head normal form. □

**Lemma 7** Let \( e \) be a \( \lambda \)-term in head normal form. There exist a type \( \rho \) and a constraint environment \( A \) such that \( \vdash_{\text{sw}} e : \rho; A \).

**Proof** A term in head normal form can be written as \( \lambda x_1 \ldots \lambda x_n. x e_1 \ldots e_m \) where \( m \) and \( n \) are two integers, \( x \) a term variable and \( e_1, \ldots, e_m \) some \( \lambda \)-terms. It is enough to show that \( x e_1 \ldots e_m \) is typable. Let \( \rho \) be a type, we have \( \vdash_{\text{sw}} x e_1 \ldots e_m : \rho; \{ x : [\rho_1] \to \cdots \to [\rho_m] \to \rho \} \). □

**Theorem 8** Let \( e \) be a \( \lambda \)-term which has a head normal form. Then there exist a type \( \rho \) and a constraint environment \( A \) such that \( \vdash_{\text{sw}} e : \rho; A \).

**Proof** There exist a term \( e' \) in head normal form such that \( e =_\beta e' \). By the lemma 7, there exist a constraint environment \( A \) and a type \( \rho \) such that \( \vdash_{\text{sw}} e' : \rho; A \). Thus by the theorem 3, we have \( \vdash_{\text{sw}} e : \rho; A \). □

**Corollary** A \( \lambda \)-term has a head normal form if and only if it is typable.

**Proof** by the theorems 7 and 8. □

14
\[
\text{Infer}(N) = \\

\]

Figure 3: Type inference algorithm

4 Type inference

In this section we present a type assignment algorithm for normal forms and we prove its soundness and completeness with respect to the inference rules defining the $\vdash_{sw_p}$ relation (cf. figure 2). Our inference algorithm is not really original, since we can find similar definitions in [6, 26, 25, 35, 17] where the principal type property in the intersection type discipline is studied.

The novelty in the work presented here is not the type assignment algorithm itself but the study of the structure of pairs inferred by this algorithm, which is developed in the further sections.

The type inference algorithm is presented in figure 3. For clarity, we do not formalize the notion of new type variable (see [16] for a precise definition). This algorithm is defined modulo the name of type variables, since we do not fix the choice of the new type variables. Moreover, one can notice that there is no notion of bound type variables.

Remark: Two non overlapped calls to Infer give disjoint types and disjoint constraint environments, since type variables used in each call to Infer are new type variables. This fact will be used in the proof of completeness of the algorithm.

The inference algorithm is sound and complete in the sense of [19], as expressed by theorems 9 and 10.

**Theorem 9** Let $N$ be a normal form, if $\text{Infer}(N) = (\rho, A)$ then $\vdash_{sw_p} N : \rho; A$.

**Proof** by structural induction on $N$.

- Case $N = x$.
  
  $\text{Infer}(x) = (\alpha, \{ x : [\alpha] \})$ and we can derive $\vdash_{sw_p} x : \alpha; \{ x : [\alpha] \}$.

- Case $N = \lambda x.N_1$.
  
  Let $(\rho_1, A_1) = \text{Infer}(N_1)$ then by induction, $\vdash_{sw_p} N_1 : \rho_1; A_1$ and $\text{Infer}(\lambda x.N_1) = (A_1(x) \rightarrow$
\( \rho_1, A_1 \setminus \{x\} \). We can therefore prove:

\[
\frac{\vdash \text{sw}_p N_1 : \rho_1; A_1}{\vdash \text{sw}_p \lambda x. N_1 : A_1(x) \to \rho_1; A_1 \setminus \{x\}}
\]

- **Case** \( N = x_{N_1} \ldots N_n \).

Let \( \alpha \) be a new type variable and for every \( i = 1, \ldots, n, (\rho_i, A_i) = \text{Infer}(N_i) \). \( \text{Infer}(x_{N_1} \ldots N_n) = (\alpha, \{x : [\rho_1] \to \cdots \to [\rho_n] \to \alpha\} + A_1 + \cdots + A_n) \)

By induction, we have \( \vdash \text{sw}_p N_i : \rho_i; A_i \) for all \( i = 1, \ldots, n \). If we write \( \rho = [\rho_1] \to \cdots \to [\rho_n] \to \alpha \), we can derive \( \vdash \text{sw}_p x : \rho; \{x : [\rho]\} \) according to the typing rule (VAR). Then we have the following derivation:

\[
\frac{\vdash \text{sw}_p x : \rho; A \quad \vdash \text{sw}_p N_1 : \rho_1; A_1}{\vdash \text{sw}_p x_1 : \rho' ; A + A_1}
\]

\[
\vdots
\]

\[
\vdash \text{sw}_p x_{N_1} \ldots N_{n-1} : [\rho_n] \to \alpha; A' \quad \vdash \text{sw}_p N_n : \rho_n; A_n
\]

\[
\vdash \text{sw}_p x_{N_1} \ldots N_n : \alpha; A + A_1 + \cdots + A_n
\]

where \( \rho' = [\rho_2] \to \cdots \to [\rho_n] \to \alpha, A = \{x : [\rho]\} \) and \( A' = A + A_1 + \cdots + A_{n-1} \).

**Theorem 10** Let \( N \) be a normal form such that \( \vdash \text{sw}_p N : \rho; A \) then \( \text{Infer}(N) = (\rho_p, A_p) \) and there exists a substitution \( S \) such that \( S(\rho_p) = \rho \) and \( S(A_p) = A \).

**Proof** by structural induction on \( N \).

- **Case** \( N = x \).

  We derive \( \vdash \text{sw}_p x : \sigma; \{x : [\sigma]\} \) for some \( \sigma \) and we have \( \text{Infer}(x) = (\alpha, \{x : [\alpha]\}) \). Then in order to have the expected result, we simply define the substitution \( S \) as \([\alpha/\sigma]\).

- **Case** \( N = \lambda x.N_1 \).

  We have derived:

  \[
  \frac{\vdash \text{sw}_p N_1 : \rho_1; A_1}{\vdash \text{sw}_p \lambda x. N_1 : A_1(x) \to \rho_1; A_1 \setminus \{x\}}
  \]

  and by induction, \( \text{Infer}(N_1) = (\rho'_1, A'_1) \) and there exists a substitution \( S \) such that \( S(\rho'_1) = \rho_1 \) and \( S(A'_1) = A_1 \). From the latter equality, we deduce that \( S(A'_1(x)) = A_1(x) \) and \( S(A'_1 \setminus \{x\}) = A_1 \setminus \{x\} \). We have therefore:

  \[
  \text{Infer}(\lambda x.N_1) = (A'_1(x) \to \rho'_1, A'_1 \setminus \{x\})
  \]

16
with \( S(A_1(x) \rightarrow \rho_1) = A_1(x) \rightarrow \rho_1 \) and \( S(A_1 \setminus \{x\}) = A_1 \setminus \{x\} \).

- Case \( N = x \quad N_1 \ldots \quad N_n \).

Because of the \((\text{VAR}_p)\) rule, the only possible derivations have the following form:

\[
\frac{}{\vdash_{\text{sw}_p} x : \rho; A} \quad \frac{}{\vdash_{\text{sw}_p} N_1 : \rho_1; A_1} \\
\vdash_{\text{sw}_p} x_1 \ldots x_n : [\rho_n] \rightarrow \alpha; A' \quad \vdash_{\text{sw}_p} N_n : \rho_n; A_n}
\]

where \( \rho = [\rho_1] \rightarrow \ldots [\rho_n] \rightarrow \alpha, \rho' = [\rho_2] \rightarrow \ldots [\rho_n] \rightarrow \alpha, A = \{x : [\rho]\} \) and \( A' = A + A_1 + \cdots + A_{n-1} \). For all \( i \in \{1, \ldots, n\} \), we deduce from the induction hypothesis, that \( \text{Infer}(N_i) = (\rho'_i, A'_i) \) and there exist \( n \) substitutions \( S_1, S_2, \ldots, S_n \) such that for all \( i \in \{1, \ldots, n\} \), \( S_i(\rho'_i) = \rho_i \) and \( S_i(A'_i) = A_i \).

Let \( \beta \) be a new type variable. \( \text{Infer}(x \quad N_1 \ldots \quad N_n) = (\beta, \{x : [[\rho'_1] \rightarrow \cdots [\rho'_n] \rightarrow \beta] + A'_1 + \cdots + A'_n\}) \)

Moreover, according to the previous remark about non overlapped calls to \( \text{Infer} \), the domains of substitutions \( S_i \) are disjoint from each other. We can therefore consider the substitution \( S' = S_1 + \cdots + S_n + [\beta/\alpha] \). We have \( S'/(\beta) = \alpha \) and \( S'/\{x : [[\rho'_1] \rightarrow \cdots [\rho'_n] \rightarrow \beta] + A'_1 + \cdots + A'_n\} = \{x : [[\rho_1] \rightarrow \cdots [\rho_n] \rightarrow \alpha] + A_1 + \cdots + A_n\} \), which implies the result. \( \Box \)

Theorem 10 states that our system has the principal type property for normal forms. Since for any given normal form, the inference algorithm gives a type and a constraint environment from which we can derive any possible type of this normal form by substitution.

As an example, type inference of \( \lambda x. \lambda y. x(y \; x) \) produces the type \( ([\alpha, [\beta] \rightarrow [\gamma] \rightarrow [\alpha] \rightarrow [\beta]) \rightarrow \gamma \). This type, as well as any other type returned by the algorithm \( \text{Infer} \), possesses a few peculiarities, the most obvious being that each type variable has exactly two occurrences: one positive and one negative. In section 4, we characterize pairs computed by the algorithm. In section 5, we will see that, given such a type (e.g. \( [\alpha, [\beta] \rightarrow [\gamma] \rightarrow [\alpha] \rightarrow [\beta] \rightarrow [\gamma] \)), one can reconstruct a \( \lambda \)-term in normal form, by (roughly speaking):

- following the arrows from left to right: that gives the outermost abstractions of the result (\( \lambda u. \lambda v. \ldots \) in our example)

- following type variables, starting from the rightmost one, in order to build the body of the normal form (\( \lambda u. \lambda v. u(v \; u) \) in this case).

In the following, the principal pair of a \( \lambda \)-term in normal form is the pair of type and constraint environment given by \( \text{Infer} \). The previous theorem justifies this terminology.

## 5 Characterization of principal pairs

In order to characterize the set of pairs of normal forms, we define a set of types \( T_p \) and a set of constraint environments \( E_p \) and we prove that the algorithm \( \text{Infer} \) produces only types and constraint environments belonging to \( T_p \) and \( E_p \) respectively. Then we restrict further these two sets to provide a complete characterization of the set of principal pairs \((\rho, A)\) given by \( \text{Infer} \).
\[
\sigma \in \mathcal{T}_{E_p} \quad ::= \quad \alpha \\
\quad \ | \quad [\tau] \rightarrow \sigma \quad \text{with} \quad \text{Type} \text{Var}(\tau) \cap \text{Type} \text{Var}(\sigma) = \emptyset
\]
\[
\tau \in \mathcal{T}_p \quad ::= \quad \alpha \\
\quad \ | \quad [\sigma_1, \ldots, \sigma_n] \rightarrow \tau \quad \text{with} \quad n \geq 0
\]
\[
A \in \mathcal{E}_p \quad ::= \quad \{} \\
\quad \ | \quad \{x : \sigma\} \\
\quad \ | \quad A_1 + A_2
\]

Figure 4: Principal types and constraint environments

5.1 Principal pairs belong to \( \mathcal{T}_p \times \mathcal{E}_p \)

In figure 4, we define \( \mathcal{T}_{E_p} \) and \( \mathcal{T}_p \) two sub-sets of \( \mathcal{T} \) and the set \( \mathcal{E}_p \) of principal constraint environments. The intersection between \( \mathcal{T}_{E_p} \) and \( \mathcal{T}_p \) is not empty, since each type variable belongs at the same time to \( \mathcal{T}_{E_p} \) and to \( \mathcal{T}_p \). Moreover, if \( \rho_1 \) and \( \rho \) belong to \( \mathcal{T}_{E_p} \cap \mathcal{T}_p \), then \( [\rho_1] \rightarrow \rho \in \mathcal{T}_{E_p} \cap \mathcal{T}_p \) since \( [\rho_1] \rightarrow \rho \) has the shape of \( [\tau] \rightarrow \sigma \) with \( \tau = \rho_1 \) and \( \sigma = \rho \) but also the shape of \( [\sigma_1, \ldots, \sigma_n] \rightarrow \tau \) with \( n = 1 \), \( \sigma_1 = \rho_1 \) and \( \tau = \rho \).

In the following, we write \( \tau, \tau', \tau_1, \ldots \) for elements of \( \mathcal{T}_{E_p} \), and \( \tau, \tau', \tau_1, \ldots \) for elements of \( \mathcal{T}_p \). When we do not want to specify whether a type belongs to \( \mathcal{T}_{E_p} \) or to \( \mathcal{T}_p \), we write it \( \rho, \rho', \rho_1, \ldots \) as for types in \( \mathcal{T}_\lambda \).

The following lemma states that principal pairs belong to \( \mathcal{T}_p \times \mathcal{E}_p \).

**Lemma 8** Let \( N \) be a normal form, if \( \text{Infer}(N) = (\tau, A) \) then \( \tau \in \mathcal{T}_p \) and \( A \in \mathcal{E}_p \).

**Proof** by induction on the structure of \( N \).

- Case \( N = x \).
  \( \text{Infer}(x) = (\alpha, \{x : [\alpha]\}) \) and we have \( \alpha \in \mathcal{T}_p \) and \( \alpha \in \mathcal{T}_{E_p} \), so \( \{x : [\alpha]\} \in \mathcal{E}_p \).

- Case \( N = \lambda x . N_1 \).
  \( \text{Infer}(N_1) = (\tau_1, A_1) \) and by induction, \( \tau_1 \in \mathcal{T}_p \) and \( A_1 \in \mathcal{E}_p \).
  If we write \( A_1(x) = [\sigma_1, \ldots, \sigma_n] \) with \( n \geq 0 \) then \( \text{Infer}(\lambda x . N_1) = ([\sigma_1, \ldots, \sigma_n] \rightarrow \tau_1, A_1 \setminus \{x\}) \). Since \( A_1 \in \mathcal{E}_p \), if \( n \geq 1 \), \( \sigma_i \in \mathcal{T}_{E_p} \) for all \( i \in \{1, \ldots, n\} \), and since \( \tau_1 \in \mathcal{T}_p \), we have \( [\sigma_1, \ldots, \sigma_n] \rightarrow \tau_1 \in \mathcal{T}_p \) for \( n \geq 0 \) and \( A_1 \setminus \{x\} \in \mathcal{E}_p \).

- Case \( N = x \ N_1 \ldots \ N_n \).
  Let \( \alpha \) be a new type variable and for all \( i \in \{1, \ldots, n\} \), \( (\tau_i, A_i) = \text{Infer}(N_i) \). Then
  \( \text{Infer}(x \ N_1 \ldots \ N_n) = (\alpha, \{x : [\tau_1] \rightarrow \cdots \rightarrow [\tau_n] \rightarrow \alpha\}) + A_1 + \cdots + A_n) \)
  Now \( \alpha \in \mathcal{T}_{E_p} \) and \( \alpha \in \mathcal{T}_p \), moreover by induction, for all \( i \in \{1, \ldots, n\} \), \( \tau_i \in \mathcal{T}_p \) and \( A_i \in \mathcal{E}_p \). Therefore we must prove that \( [\tau_1] \rightarrow \cdots \rightarrow [\tau_n] \rightarrow \alpha \in \mathcal{T}_{E_p} \), which is immediate. \( \Box \)

If we regard \( \text{Infer} \) as a function from the set of normal forms to the set of pairs \( (\tau, A) \), the set of pairs \( (\tau, A) \) such that there exists a normal form \( N \) which verifies \( \text{Infer}(N) = (\tau, A) \) is written
\textbf{Range} (Infer). So we can restate the previous lemma in the following way:

\[ \text{Range(Infer)} \subseteq T_p \times \mathcal{E}_p \]

5.2 A-types

In the following, we always consider pairs consisting of a type and a constraint environment. To handle types and type constraints consistently, we introduce \textit{A-types}, using a double arrow in order to write type constraints negatively. Formally, we define the set of A-types by the following grammar:

\[
T := [\sigma_1, \ldots, \sigma_n] \Rightarrow \tau \text{ with } n \geq 0 \\
| [\sigma_1, \ldots, \sigma_n] \Rightarrow \text{ with } n \geq 1
\]

where \([\sigma_1, \ldots, \sigma_n]\) is a multi-set of elements of \(T_{E_p}\). The function \textit{TypeVar}, returning the set of type variables of a type, is naturally extended to A-types.

Since the algorithm \textit{Infer} returns a pair \((\tau, A)\), in the following we often want to go from this pair to the corresponding A-type. So we define an operation which simply consists of collecting all constraints from a constraint environment in order to obtain a single multi-set of type constraints.

\textbf{Definition} Let \(A\) be a constraint environment, we define \(\overline{A}\) by induction on the structure of \(A\):

- if \(A = \{\}\), then \(\overline{A} = []\)
- if \(A = \{x : [\sigma]\}\), then \(\overline{A} = [\sigma]\)
- if \(A = A_1 + A_2\), then \(\overline{A} = \overline{A_1} \cup \overline{A_2}\)

So, for any type \(\tau\) and any constraint environment \(A\), \(\overline{A} \Rightarrow \tau\) is an A-type.

\textbf{Definition} We say that \(T'\) is \textit{held} in \(T\), if

- \(T = [\sigma_1, \ldots, \sigma_n] \Rightarrow \tau\)
- and \(T'\) has one of the following forms:
  - \([\sigma_{i_1}, \ldots, \sigma_{i_p}] \Rightarrow \tau\)
  - \([\sigma_{i_1}, \ldots, \sigma_{i_p}] \Rightarrow\)

where \([\sigma_{i_1}, \ldots, \sigma_{i_p}]\) is a sub-multi-set (non empty in the second case) of \([\sigma_1, \ldots, \sigma_n]\). Moreover, if \(T'\) is held in \(T\) and distinct from \(T\), we say that \(T'\) is \textit{strictly held} in \(T\).

Extending the notion of left sub-terms of a type we define for each A-type \(T\), the set \(L_0(T)\) of left sub-terms of \(T\) by induction on the structure of \(T\):

- if \(T = [\sigma_1, \ldots, \sigma_n] \Rightarrow \tau\) then \(L_0(T) = \{\sigma_1, \ldots, \sigma_n\} \cup L_0(\tau)\)
- if \(T = [\sigma_1, \ldots, \sigma_n] \Rightarrow\) then \(L_0(T) = \{\sigma_1, \ldots, \sigma_n\}\).

We also extend to A-types the notion of sign of occurrences. Let \(T\) be an A-type and \(\alpha\) a type variable. The positive (respectively negative) occurrences of \(\alpha\) in \(T\) are defined by induction on the structure of \(T\):

19
if \( T = [\sigma_1, \ldots, \sigma_n] \Rightarrow \tau \), then the positive (respectively negative) occurrences of \( \alpha \) in \( T \) are the positive (respectively negative) occurrences of \( \alpha \) in \( \tau \) and the negative (respectively positive) occurrences of \( \alpha \) in \( \sigma_i \) for \( i = 1, \ldots, n \).

- if \( T = [\sigma_1, \ldots, \sigma_n] \Rightarrow \), then the positive (respectively negative) occurrences of \( \alpha \) in \( T \) are the negative (respectively positive) of \( \alpha \) in \( \sigma_i \) for \( i = 1, \ldots, n \).

In order to characterize the structure of principal pairs, we define three structural properties on pairs. The first of them expresses that the inference algorithm always introduces two occurrences of a new type variable with different signs. The second one is less significant but is used in the reconstruction algorithm. The last one is used to express that the inference algorithm Infer produces the minimal constraint environment.

**Definition** An A-type \( T \) is closed if each type variable of \( TypeVar(T) \) has exactly one positive occurrence and one negative occurrence in \( T \).

**Definition** Let \( T = [\sigma_1, \ldots, \sigma_n] \Rightarrow \tau \) be an A-type. \( T \) is finally closed if the variable \( \alpha \) in the final occurrence of \( \tau \) is also in the final occurrence of a type which is element of \( L_0(T) \).

**Definition** Let \( T \) be an A-type. \( T \) is minimally closed if there is no closed A-type strictly held in \( T \).

5.3 Properties of principal typing

The following definition gives a short way to talk about the three previous properties simultaneously.

**Definition** Let \( T = [\sigma_1, \ldots, \sigma_n] \Rightarrow \tau \) be an A-type. We say that \( T \) is complete if

- \( T \) is closed
- \( T \) is finally closed
- \( T \) is minimally closed.

**Example:** \( T = [[[\alpha, [\alpha] \rightarrow \beta] \rightarrow \beta] \rightarrow \gamma, [\delta] \rightarrow \delta] \Rightarrow \gamma \) is closed, finally closed but not minimally closed because the A-type \( [[[\alpha, [\alpha] \rightarrow \beta] \rightarrow \beta] \rightarrow \gamma] \Rightarrow \gamma \) is closed and strictly held in \( T \). So, \( T \) is not complete. However, the A-type \( [[[\alpha, [\alpha] \rightarrow \beta] \rightarrow \beta] \rightarrow \gamma \Rightarrow \gamma \) is complete.

**Lemma 9** Let \( N \) be a normal form, if \( Infer(N) = (\tau, A) \), then \( \overline{A} \Rightarrow \tau \) is complete.

**Proof** by structural induction on \( N \).

- Case \( N = x \).

Then \( Infer(x) = (\alpha, \{ x : [\alpha] \}) \) and \( \overline{A} \Rightarrow \tau = [\alpha] \Rightarrow \alpha \). Thus we have:

  - \( \alpha \) is the only type variable of \( A \Rightarrow \tau \) and it has a positive occurrence and a negative occurrence in \( \overline{A} \Rightarrow \tau \). So \( [\alpha] \Rightarrow \alpha \) is closed.
  
  - \( \alpha \) is the final occurrence of \( \alpha \) and \( L_0(\overline{A} \Rightarrow \tau) = \{ \alpha \} \). Therefore \( [\alpha] \Rightarrow \alpha \) is finally closed.
  
  - The only A-types strictly held in \( \overline{A} \Rightarrow \tau \) are \( [\alpha] \Rightarrow \) and \( [\alpha] \Rightarrow \alpha \) which are not closed. So \( [\alpha] \Rightarrow \alpha \) is minimally closed.
• Case $N = \lambda x. N_1$.

Let $(\tau_1, A_1) = \text{Infer}(N_1)$. We deduce from the induction hypothesis, that $\overline{A_1} \Rightarrow \tau_1$ is complete.

If we write $A_1(x) = [\sigma^1, \ldots, \sigma^n]$ with $n \geq 0$ then $\text{Infer}(\lambda x. N_1) = ([\sigma^1, \ldots, \sigma^n] \rightarrow \tau_1, A_1 \setminus \{x\})$.

- $\text{TypeVar}(A_1 \setminus \{x\} \Rightarrow [\sigma^1, \ldots, \sigma^n] \rightarrow \tau_1) = \text{TypeVar}(\overline{A_1} \Rightarrow \tau_1)$. Furthermore, for $i = 1, \ldots, n$, the occurrences of type variables in $\sigma^i$ keep the same sign in $A_1 \setminus \{x\} \Rightarrow [\sigma^1, \ldots, \sigma^n] \rightarrow \tau_1$ as in $\overline{A_1} \Rightarrow \tau_1$. Hence the A-type $A_1 \setminus \{x\} \Rightarrow [\sigma^1, \ldots, \sigma^n] \rightarrow \tau_1$ is closed since $\overline{A_1} \Rightarrow \tau_1$ is closed by induction.

- On the other hand, the final occurrences of the two types $[\sigma^1, \ldots, \sigma^n] \rightarrow \tau_1$ and $\tau_1$ are the same and $L_0(A_1 \setminus \{x\} \Rightarrow [\sigma^1, \ldots, \sigma^n] \rightarrow \tau_1) = L_0(A_1 \Rightarrow \tau_1)$. Therefore, by induction, the A-type $A_1 \setminus \{x\} \Rightarrow [\sigma^1, \ldots, \sigma^n] \rightarrow \tau_1$ is finally closed.

- Let $T$ be an A-type strictly held in the A-type $A_1 \setminus \{x\} \Rightarrow [\sigma^1, \ldots, \sigma^n] \rightarrow \tau_1$, then there exists $T'$ strictly held in $\overline{A_1} \Rightarrow \tau_1$ such that $\text{TypeVar}(T) = \text{TypeVar}(T')$. Furthermore, since the occurrences of type variables in $\overline{A_1} \Rightarrow \tau_1$ keep the same sign as in $A_1 \setminus \{x\} \Rightarrow [\sigma^1, \ldots, \sigma^n] \rightarrow \tau_1$, for all closed $T$ strictly held in $A_1 \setminus \{x\} \Rightarrow [\sigma^1, \ldots, \sigma^n] \rightarrow \tau_1$, there exists a closed $T'$ strictly held in $\overline{A_1} \Rightarrow \tau_1$. Hence by induction, there does not exist any closed A-type strictly held in $A_1 \setminus \{x\} \Rightarrow [\sigma^1, \ldots, \sigma^n] \rightarrow \tau_1$. Therefore, $A_1 \setminus \{x\} \Rightarrow [\sigma^1, \ldots, \sigma^n] \rightarrow \tau_1$ is minimally closed.

• Case $N = x_1 N_1 \ldots N_n$.

Let $\alpha$ be a new type variable and for $i = 1, \ldots, n$, $(\tau_i, A_i) = \text{Infer}(N_i)$. Then $\text{Infer}(x_1 N_1 \ldots N_n) = (\alpha, \{x : [[\tau_1] \rightarrow \cdots \rightarrow [\tau_n] \rightarrow \alpha]\} + A_1 + \cdots + A_n)$. We write $A = \{x : [[\tau_1] \rightarrow \cdots \rightarrow [\tau_n] \rightarrow \alpha]\} + A_1 + \cdots + A_n$.

By induction for all $i \in \{1, \ldots, n\}$, $\overline{A_i} \Rightarrow \tau_i$ is complete.

- $\text{TypeVar}(A \Rightarrow \alpha) = \bigcup_{i=1}^n \text{TypeVar}(\overline{A_i} \Rightarrow \tau_i \cup \{\alpha\})$. Now, if $\beta \in \bigcup_{i=1}^n \text{TypeVar}(\overline{A_i} \Rightarrow \tau_i)$ for all $i \in \{1, \ldots, n\}$, then the occurrences of $\beta$ have the same sign in $\overline{A_i} \Rightarrow \tau_i$ and in $A \Rightarrow \alpha$. Furthermore, $\alpha$ has a positive occurrence and a negative occurrence in $\overline{A} \Rightarrow \alpha$. So $\overline{A} \Rightarrow \alpha$ is closed.

- The final occurrence of $\alpha$ is also the final occurrence of $[\tau_1] \rightarrow \cdots \rightarrow [\tau_n] \rightarrow \alpha$ which belongs to $L_0(\overline{A} \Rightarrow \alpha)$. So $\overline{A} \Rightarrow \alpha$ is finally closed.

- Let $T$ be an A-type held in $\overline{A} \Rightarrow \alpha$. For $i = 1, \ldots, n$, the sets $\text{TypeVar}(\overline{A_i} \Rightarrow \tau_i)$ have no common type variables, since they result from disjoint calls to $\text{Infer}$. Furthermore, for all $i \in \{1, \ldots, n\}$, $\overline{A_i} \Rightarrow \tau_i$ is minimally closed.

Since $T$ is closed, every type of $A_i$ and every $\tau_i$ must occur in $T$. Now the only way for $T$ to have an occurrence of each $\tau_i$ is to have an occurrence of $[\tau_1] \rightarrow \cdots \rightarrow [\tau_n] \rightarrow \alpha$. But if $[\tau_1] \rightarrow \cdots \rightarrow [\tau_n] \rightarrow \alpha$ occurs in $T$ and if $T$ is closed then $\alpha$ must also occur in $T$ since $\alpha$ is a new type variable which occurs neither in $A_i$ nor in $\tau_i$.

We conclude that $T$ is $\overline{A} \Rightarrow \alpha$ and therefore that $\overline{A} \Rightarrow \alpha$ is minimally closed.
The next definition specifies the structure of principal pairs. Intuitively, we want to say that for any given normal form, we can find the principal pair of its sub-terms from its principal pair. Since it is easier to study an A-type than a pair \((\tau, A)\), we formalize our intuition on A-types.

**Definition** Let \(T\) be a A-type. We say that \(T\) is principal if it is complete and if it is one of the following cases:

- \(T = [\alpha] \Rightarrow \alpha\).
- \(T = [\sigma_1, \ldots, \sigma_n] \Rightarrow \alpha\) and \(\exists i \in \{1, \ldots, n\}\) such that \(\sigma_i\) has the shape \([\tau_1] \rightarrow \cdots \rightarrow [\tau_p] \rightarrow \alpha\) with \(p > 0\) and there exists a partition \((E_j)_{j=1}^p\) of the multi-set \([\sigma_1, \ldots, \sigma_{i-1}, \sigma_{i+1}, \ldots, \sigma_n]\) such that each \(E_j \Rightarrow \tau_j\) is principal.
- \(T = [\sigma_1, \ldots, \sigma_n] \Rightarrow [\sigma_{n+1}, \ldots, \sigma_{n+p}] \rightarrow \tau'\) and 
  \([\sigma_1, \ldots, \sigma_n, \sigma_{n+1}, \ldots, \sigma_{n+p}] \Rightarrow \tau'\) is principal.

One may notice a similarity between the three cases above and the three cases defining normal forms. This will be made formal in section 5.

**Remark:** A complete A-type is not necessarily principal. For example, the A-type defined by 
\(T = [[[\gamma] \rightarrow \beta] \rightarrow \alpha; \gamma] \rightarrow [[[\beta] \rightarrow \delta] \rightarrow \delta] \Rightarrow \alpha\) is complete, but not principal, since \([[\gamma] \rightarrow [[[\beta] \rightarrow \delta] \rightarrow \delta] \Rightarrow \gamma] \rightarrow \beta\) is not finally closed, therefore not principal.

**Lemma 10** Let \(N\) be a normal form. If \(\text{Infer}(N) = (\tau, A)\) then \(\overline{A} \Rightarrow \tau\) is principal.

**Proof** by structural induction on \(N\).

Thanks to the previous lemma, in any case \(\overline{A} \Rightarrow \tau\) is complete.

- Case \(N = x\).

Then \(\text{Infer}(N) = (\alpha, \{x : [\alpha]\})\) and \([\alpha] \Rightarrow \alpha\) is principal by definition.

- Case \(N = \lambda x. N_1\).

Let \((\tau_1, A_1) = \text{Infer}(N_1)\). By induction, \(\overline{A_1} \Rightarrow \tau_1\) is principal.

If we write \(A_1(x) = [\sigma_1, \ldots, \sigma_n]\) then we have \(\text{Infer}(N) = ([\sigma_1, \ldots, \sigma_n] \rightarrow \tau_1, A_1 \setminus \{x\})\). By definition of a principal A-type, in order to prove that the A-type \(A_1 \setminus \{x\} \Rightarrow [\sigma_1, \ldots, \sigma_n] \rightarrow \tau_1\) is principal, it is enough to prove that \(A_1 \setminus \{x\} \cup [\sigma_1, \ldots, \sigma_n] \Rightarrow \tau_1\) is principal. Now \(A_1 \setminus \{x\} \cup [\sigma_1, \ldots, \sigma_n] = \overline{A_1}\) and we conclude with the induction hypothesis.

- Case \(N = x_1, \ldots, x_n\).

Let \(\alpha\) be a new type variable and for \(i = 1, \ldots, n\), \((\tau_i, A_i) = \text{Infer}(N_i)\). By induction each \(\overline{A_i} \Rightarrow \tau_i\) is principal and in particular complete. Furthermore, we have \(\text{Infer}(N) = (\alpha, \{x : [\tau_1] \rightarrow \cdots \rightarrow [\tau_n] \rightarrow \alpha\} \cup A_1 + \cdots + A_n\)\). This is an instance of the second case defining principal A-types and we must prove that there exists a partition of the multi-set \(A_1 + \cdots + A_n\) into \(n\) sub-multi-sets \(E_1, \ldots, E_n\) such that each \(E_i \Rightarrow \tau_i\) is principal. \((\overline{A_i})_{i=1}^n\) is a partition of \(A_1 + \cdots + A_n\) such that each \(\overline{A_i} \Rightarrow \tau_i\) is principal by the induction hypothesis.

Thus \(\{x : [[\tau_1] \rightarrow \cdots \rightarrow [\tau_n] \rightarrow \alpha]\} \cup A_1 + \cdots + A_n \Rightarrow \alpha\) is principal.

If we write \(P = \{(\tau, A) / \tau \in T_p, A \in E_p \text{ and } \overline{A} \Rightarrow \tau\text{ is principal}\}\), the previous lemma proves the inclusion:

\[
\text{Range(Infer)} \subset P
\]
\[ R(\tau, A) = \]

- **Case** \( (\alpha, \{\}) \)
  fail
- **Case** \( (\alpha, A) \)
  \( \text{let } \{(\tau^1, x_1), \ldots, (\tau^m, x_m)\} = F(\alpha, A) \)
  \( \text{if } m = 1 \text{ and } \tau^1 = [\tau_1] \rightarrow \cdots \rightarrow [\tau_n] \rightarrow \alpha \)
  \( \text{then if for } i = 1, \ldots, n, \text{ there exists } A_i \subset A \text{ such that } \overline{A}_i \Rightarrow \tau_i \text{ is principal} \)
  \( \text{then let } (N_1, A'_1) = R(\tau_1, A_1) \)
  \( \vdots \)
  \( (N_n, A'_n) = R(\tau_n, A_n) \)
  \( A' = \{x : [[\tau_1] \rightarrow \cdots \rightarrow [\tau_n] \rightarrow \alpha] + A_1 + \cdots + A_n \} \)
  \( \text{return } (x \ N_1 \ \ldots \ N_n, A \setminus A' + A'_1 + \cdots + A'_n) \)
  else fail
- else fail
- **Case** \( ([\sigma^1, \ldots, \sigma^n] \rightarrow \tau', A) \)
  \( \text{let } x \text{ be a new term variable} \)
  \( A' = A + \{x : [\sigma^1, \ldots, \sigma^n]\} \)
  \( (N, A'') = R(\tau', A') \)
  \( \text{if } A''(x) = [] \)
  \( \text{then return } (\lambda x. N, A'') \)
  else fail

Figure 5: Reconstruction algorithm
6 Reconstruction of normal forms

In order to characterize the principal pairs of normal forms, we give an algorithm \( \mathcal{R} \) which, given a type and a constraint environment, constructs a normal form typable with this type and this constraint environment.

Let \( \alpha \) be a type variable and \( A \) be a constraint environment. We write \( F(\alpha, A) \) the set of types which belong to \( A \) and have \( \alpha \) as final occurrence. More precisely: \( F(\alpha, A) = \{(\tau, x) / \tau \in A(x) \text{ and } \alpha \text{ is the final occurrence of } \tau \} \)

We define the reconstruction algorithm \( \mathcal{R} \) in figure 5. Since we make no hypotheses on \( \tau \) or \( A \) in the definition of \( \mathcal{R} \), we must justify that \( \mathcal{R} \) is always defined for a principal pair. So we prove in the following remarks that the application of \( \mathcal{R} \) to a principal pair never leads to a case of failure.

**Remarks:**

- \{ \} \Rightarrow \alpha \text{ is not closed and so the first case of } \mathcal{R} \text{ is impossible with a pair } (\tau, A) \text{ belonging to } \mathcal{P}.
- If \( F(\alpha, A) = \{((\tau^1, x_1), \ldots, (\tau^m, x_m)) \} \) with \( m \neq 1 \), in the case \( (\alpha, A) \) then \( \overline{A} \Rightarrow \alpha \) is not finally closed. Therefore this case is impossible with a pair \( (\tau, A) \in \mathcal{P} \).
- If \( \mathcal{R}(\tau, A) = (N, B) \) then \( B \subseteq A \). The proof is immediate by induction on the number of calls to \( \mathcal{R} \).

**Lemma 11** If \( (\tau, A) \in \mathcal{P} \) then \( \mathcal{R}(\tau, A) = (N, A') \) is well defined and \( A' = \{ \} \).

**Proof** by induction on the number of calls to \( \mathcal{R} \).

- Case \( (\alpha, A) \).

Let \( \{([\tau_1] \rightarrow \cdots \rightarrow [\tau_n] \rightarrow \alpha, x)\} = F(\alpha, A) \). We have therefore \( A = \{x : [[\tau_1] \rightarrow \cdots \rightarrow [\tau_n] \rightarrow \alpha]\} + B \) for some constraint environment \( B \).

Moreover, if \( F(\alpha, A) = \{([\tau_1] \rightarrow \cdots \rightarrow [\tau_n] \rightarrow \alpha, x)\} \) with \( n = 0 \), then we have \( \mathcal{R}(\alpha, A) = (x, A \setminus \{x : [\alpha]\}) \). So \( \mathcal{R}(\alpha, A) = (x, \{\}) \) is well defined.

We remark that if \( n = 0 \) then \( \mathcal{R}(\alpha, A) = (x, A \setminus \{x : [\alpha]\}) \). Now for an element of \( \mathcal{P} \), \( \overline{A} \Rightarrow \alpha \) is minimally closed and \( A = \{x : [\alpha]\} \). So \( \mathcal{R}(\alpha, A) = (x, \{\}) \) is well defined.

Now we suppose \( n \geq 1 \).

By hypothesis, we know that \( \overline{A} \Rightarrow \alpha \) is principal. Thus, by definition of a principal A-type, there exists a partition \( (E_i)_{i=1 \ldots n} \) of \( B \) such that each \( E_i \Rightarrow \tau_i \) is principal. Now we can construct from \( B \) and for each \( E_i \), a constraint environment \( A_i \) such that \( \overline{A_i} = E_i \).

Therefore there exist \( n \) sub-environments \( A_1, \ldots, A_n \) of \( B \) such that \( \overline{A_i} \Rightarrow \tau_i \) is principal for all \( i \in \{1, \ldots, n\} \). Since each \( A_i \) is a sub-environment of \( B \), it is also a sub-environment of \( A \). So in order to prove that \( \mathcal{R}(\tau, A) \) is well defined, it is enough to prove that \( \mathcal{R}(\tau_i, A_i) \) is well defined for all \( i \in \{1, \ldots, n\} \), by definition of \( \mathcal{R} \).

Since each \( \overline{A_i} \Rightarrow \tau_i \) is principal, we can apply the induction hypothesis to \( \mathcal{R}(\tau_i, A_i) \) for \( i = 1, \ldots, n \). Thus for \( i = 1, \ldots, n \), \( \mathcal{R}(\tau_i, A_i) = (N_i, A_i') \) is well defined and \( A_i' = \{\} \).

From this, we deduce that \( \mathcal{R}(\alpha, A) = (x \ N_1 \ldots \ N_n, A') \) is well defined with \( A' = A \setminus \{x : [[\tau_1] \rightarrow \cdots \rightarrow [\tau_n] \rightarrow \alpha]\} \).
\[ \cdots \rightarrow [\tau_n \rightarrow \alpha] + A_1 + \cdots + A_n \} + \{ \} \]

Now if we write \( A'' = \{ x : [[\tau_1] \rightarrow \cdots \rightarrow [\tau_n] \rightarrow \alpha] + A_1 + \cdots + A_n \}, \) we have \( A'' = A. \)

By definition of \( A \) and since \( \{(\tau_1) \rightarrow \cdots \rightarrow [\tau_n] \rightarrow \alpha, x\} = F(\alpha, A) \) we have \( \overline{A''} \subseteq \overline{A}. \) Moreover, \( \overline{A''} \Rightarrow \alpha \) is closed, because each \( \overline{A_i} \Rightarrow \tau_i \) is closed by definition of a principal A-type, because the sign of type variable occurrences in \( \overline{A_i} \Rightarrow \tau_i \) does not change in \( \overline{A''} \Rightarrow \alpha \) and because \( \alpha \) has exactly one positive occurrence and one negative occurrence in \( \overline{A''} \Rightarrow \alpha. \) But \( \overline{A''} \Rightarrow \alpha \) is held in \( \overline{A} \Rightarrow \alpha. \) Now by hypothesis, \( \overline{A} \Rightarrow \alpha \) is minimally closed, so \( \overline{A''} \Rightarrow \alpha \) can't be strictly held in \( \overline{A} \Rightarrow \alpha \) and we have: \( A = \{ x : [[\tau_1] \rightarrow \cdots \rightarrow [\tau_n] \rightarrow \alpha] + A_1 + \cdots + A_n \}. \) Therefore \( A' = A \setminus A'' = \{ \}. \)

- Case \( ([\sigma_1, \ldots, \sigma_n] \rightarrow \tau', A). \)

Let \( A' = \{ x : [\sigma_1, \ldots, \sigma_n] \rightarrow \tau' \} + A. \) Since \( \overline{A} \Rightarrow [\sigma_1, \ldots, \sigma_n] \rightarrow \tau' \) is principal, \( \overline{A} \Rightarrow \tau' \) is also principal. Thus by induction, \( R(\tau', A') = (N, A'') \) is well defined and \( A'' = \{ \}. \) Now \( \{\}(x) = [], \) so \( R([\sigma_1, \ldots, \sigma_n] \rightarrow \tau', A) = (\lambda x. N, A'') \) is well defined by definition of \( R, \) and \( A'' = \{ \}. \)

From now on, for each \( (\tau, A) \in P, \) we can consider the result of \( R(\tau, A) \) without verifying its existence. Moreover, in the following, if the pair \( (\tau, A) \) belongs to \( P, \) we write \( R(\tau, A) = N \) instead of \( R(\tau, A) = (N, \{\}). \)

**Lemma 12** Let \( (\tau, A) \in P \) and \( N = R(\tau, A) \) then \( Infer(N) = (\tau, A). \)

**Proof** by induction on the number of calls to \( R. \)

- Case \( (\alpha, A). \)

Let \( \{\{(\tau_1) \rightarrow \cdots \rightarrow [\tau_n] \rightarrow \alpha, x\} = F(\alpha, A). \) By definition of \( R \) and by lemma 11, we have \( R(\alpha, A) = x N_1 \cdots N_n. \) Moreover, as we did in the proof of lemma 11, one can show that there exist \( (A_i)_{i=1,\ldots,n} \) sub-environments of \( A \) such that \( \overline{A_i} \Rightarrow \tau_i \) is principal for \( i = 1, \ldots, n \) and \( A = \{ x : [[\tau_1] \rightarrow \cdots \rightarrow [\tau_n] \rightarrow \alpha] \} + A_1 + \cdots + A_n. \) So we can apply the induction hypothesis to each call of \( R \) with \( (\tau_i, A_i). \) It follows that if we write \( R(\tau_i, A_i) = N_i \) then \( Infer(N_i) = (\tau_i, A_i) \) for all \( i \in \{1, \ldots, n\}. \)

By definition of \( Infer, \) we have \( Infer(x N_1 \cdots N_n) = (\alpha, \{ x : [[\tau_1] \rightarrow \cdots \rightarrow [\tau_n] \rightarrow \alpha] \} + A_1 + \cdots + A_n). \) Since \( A = \{ x : [[\tau_1] \rightarrow \cdots \rightarrow [\tau_n] \rightarrow \alpha] \} + A_1 + \cdots + A_n, \) we finally have \( Infer(x N_1 \cdots N_n) = (\alpha, A). \)

- Case \( ([\sigma_1, \ldots, \sigma_n] \rightarrow \tau', A). \)

Let \( A' = \{ x : [\sigma_1, \ldots, \sigma_n] \rightarrow \tau', A \} \) where \( x \) is a new term variable.

Since \( \overline{A} \Rightarrow [\sigma_1, \ldots, \sigma_n] \rightarrow \tau' \) is principal, \( \overline{A} \Rightarrow \tau' \) is also principal. Thus, we can apply the induction hypothesis, if \( R(\tau', A') = N \) then \( Infer(N) = (\tau', A'). \) Now \( A'(x) = [\sigma_1, \ldots, \sigma_n] \) because \( x \) is a term variable which does not belong to the domain of \( A. \) We deduce from this that \( Infer(\lambda x. N) = ([\sigma_1, \ldots, \sigma_n] \rightarrow \tau', A' \setminus \{ x\}). \) Since \( A' \setminus \{ x\} = A, \) we can conclude.

The previous lemma gives the opposite inclusion of lemma 10. We can now completely characterize the set of principal pairs.

**Theorem 11** \( Range(\text{Infer}) = P \) in other words: The types and the constraint environments inferred for normal forms are exactly the pairs \( (\tau, A) \) such that \( \overline{A} \Rightarrow \tau \) is principal.

**Proof**
\[ \nu \in \mathcal{T}_{E_g} := \alpha \]

with \( n > 0 \), \( \forall i \in \{1, \ldots, n\}, \mu_i \in \mathcal{T}_g \), \( \text{TypeVar}(\mu_i) \cap \text{TypeVar}(\nu) = \emptyset \) and \( \forall j \in \{1, \ldots, n\} \) such that \( j \neq i \), \( \text{TypeVar}(\mu_i) \cap \text{TypeVar}(\mu_j) = \emptyset \)

\[ \mu \in \mathcal{T}_g := \alpha \]

with \( n \geq 0 \) and \( \forall i \in \{1, \ldots, n\}, \nu_i \in \mathcal{T}_{E_g} \)

\[ A \in \mathcal{E}_g := \{ \} \]

\[ \left| \{ x : [\nu] \} \right| \]

\[ A_1 + A_2 \]

Figure 6: Ground types and constraint environments

The lemma 10 states \( \text{Range}(\text{Infer}) \subset \mathcal{P} \). Thus, we must just prove that for any pair \((\tau, A) \in \mathcal{P}\), there exists a normal form \( N \) such that \( \text{Infer}(N) = (\tau, A) \).

Let \((\tau, A)\) be an element of \( \mathcal{P} \). By lemma 11, \( \mathcal{R}(\tau, A) \) exists and is a normal form written \( N \) and by lemma 12, \( \text{Infer}(N) = (\tau, A) \). So \( \mathcal{P} \subset \text{Range}(\text{Infer}) \) and we can conclude.\( \square \)

The theorem 11 states the equality \( \text{Range}(\text{Infer}) = \mathcal{P} \)

7 Ground pairs

We now consider a type assignment relation with a more general inference rule for variables. Our work rejoins here S. van Bakel’s article [35]. In his paper, S. van Bakel defines an intersection type system close to the one introduced in [1] with the same partial order relation on types. But before considering intersections as types, he defines a sub-set of strict types where intersections occur only on the left hand side of arrows. This set of strict types is equivalent to the set of types presented here. He studies the existence of principal types for this system. He was induced to define several sub-sets of the set of pairs of a type and a basis, ordered by inclusion. The smallest is the set of principal pairs which corresponds to set \( \mathcal{P} \) in our work. Van Bakel’s set of ground pairs is equivalent to the set of ground pairs that we define in this section. It is the sub-set of pairs closed under expansion. Because of the partial order relation, van Bakel uses an extra sub-set: the set of primitive pairs, closed under lifting. (This operation is necessary to take into account the inference rule that deals with the partial order relation.) Finally, his set of pairs is closed under substitution.

Here we only distinguish the set of principal pairs and ground pairs. We obtain the same final result as S. van Bakel: all normalizable \( \lambda \)-terms have a principal type, but our definition of expansion and our proofs are much simpler. We also describe in detail the structure of ground pairs.

7.1 B-types

In figure 6 we give mutually recursive definitions of \( \mathcal{T}_{E_g}, \mathcal{T}_g \) and \( \mathcal{E}_g \), extending \( \mathcal{T}_p, \mathcal{T}_p \) and \( \mathcal{E}_p \) respectively. \( \mathcal{T}_g \) is the set of ground types and \( \mathcal{E}_g \) is the set of ground constraint environments.
From now on, metavariables $\nu$ and $\mu$ denote elements of $T_{E_g}$ and $T_g$ respectively.

In section 4, we defined the sign of an occurrence, the final occurrence and left sub-terms for principal types. We can easily extend these notions to ground types. Since these definitions do not present any difficulty, we do not give them formally.

In order to link types and constraint environments and to write negatively type constraints, we defined A-types from principal types and principal constraint environments. With the same motivations, we define B-types from ground types and ground constraint environments, in the following way:

$$U ::= [\nu_1, \ldots, \nu_n] \Rightarrow \mu \text{ with } n \geq 0$$

$$U ::= [\nu_1, \ldots, \nu_n] \Rightarrow \text{ with } n \geq 1$$

Since the definition of B-types is an obvious extension of the definition of A-types, we deduce without difficulty, the definitions of closed, minimally closed, finally closed and complete B-types, from the corresponding definitions on A-types.

**Definition** We say that $U$ is a ground B-type if $U$ is complete and if it is one of the following forms:

- $U = [\rho] \Rightarrow \rho$ with $\rho \in T_g \cap T_{E_g}$.
- $U = [\nu_1, \ldots, \nu_n] \Rightarrow \alpha$ and $\exists i \in \{1, \ldots, n\}$ such that $\nu_i$ has the following shape

  $$[\mu_1^1, \ldots, \mu_n^1] \rightarrow \cdots \rightarrow [\mu_1^p, \ldots, \mu_p^n] \rightarrow \alpha$$

  with $p > 0$, and $\exists (E_j^k)_{j=1 \ldots p, k=1 \ldots n}$, a partition of the multi-set $[\nu_1, \ldots, \nu_i-1, \nu_i+1, \ldots, \nu_n]$ such that each $E_j^k \Rightarrow \mu_j^k$ is a ground B-type.

- $U = [\nu_1, \ldots, \nu_n] \Rightarrow [\nu_{n+1}, \ldots, \nu_{n+p}] \rightarrow \mu'$ with $[\nu_1, \ldots, \nu_n, \nu_{n+1}, \ldots, \nu_{n+p}] \Rightarrow \mu'$ a ground B-type.

**Remark:** The partition $(E_j^k)_{j=1 \ldots p, k=1 \ldots n}$ is unique. Since $U$ is closed, each type variable has only two occurrences in $U$ and we have not the choice of the definition of each $E_j^k$.

In the same way as we have defined the set $P$ of principal pairs, we define the set $G$ of ground pairs, by $G = \{(\mu, A)/\mu \in T_g, A \in E_g \text{ and } A \Rightarrow \mu \text{ is a ground B-type}\}$.

We can prove, by induction on the structure of A-types, the following inclusion:

$$P \subset G$$

### 7.2 Expansions

In order to simplify the definition of expansion, we need to describe several further notions and prove some properties about the structure of ground B-types. In fact, expansion is a complex operation on pairs. As S. van Bakel explains in [35], the expansion of a sub-term $\rho$ of a type $\rho'$ replaces the occurrences of $\rho$ in $\rho'$ by a number of copies of that sub-term. To be applied an expansion must therefore specify the type to be expanded and the number of necessary copies.

Intuitively, expansion corresponds to the duplication of the sub-derivation of the argument $e_2$ in the use of the inference rule (APP) for a term $e_1 e_2$. So it is not enough to duplicate one type: we must also copy all the types of this sub-derivation. Until now, this point was the source of the complexity of the definitions of expansion [6, 26, 25, 35]. Even if the need of duplicating more
than one type is well understood, the definition of the set of types to be copied, is still a difficult problem. So far, no convincing justification has been given.

The contribution of this section is precisely the definition of this problematic set of types. The justification of this definition is obvious according to the previous results about the structure of principal and ground types.

The notion of left sub-terms does not take into account the full recursive structure of a type. We now define a notion of generalized left sub-terms, following the recursive structure of types to consider all possible sub-terms which are to the left of an arrow at any level in the recursive structure of a type.

**Definition** Let $U$ be a B-type, we define the set $\mathcal{L}(U)$ of generalized left sub-terms of $U$ in the following way:

- $L_0(U)$ is defined as for A-types
- $\forall n > 0, \ L_n(U) = \bigcup_{\rho \in L_{n-1}(U)} L_0(\rho)$
- $\mathcal{L}(U) = \bigcup_{n \geq 0} L_n(U)$

The next lemma precises the structure of $\rho$ in a B-type $U = [\rho] \Rightarrow \rho$.

**Lemma 13** Let $U = [\rho] \Rightarrow \rho$ be a ground B-type and $\rho'$ a sub-term of $U$ then $\rho'$ has two occurrences in $U$, one such that $\rho'' \in T_g$ and one such that $\rho' \in T_E_g$.

**Proof**

- If $\rho' = \rho$ then $\rho$ verifies the property by definition of a B-type.
- Otherwise $\rho = [\rho_1, \ldots, \rho_n] \rightarrow \rho''$ where by definition of a ground B-type, $\rho_i$ has no common type variable neither with the other $\rho_j$ nor with $\rho''$. $\rho'$ is a sub-term of $\rho_1, \ldots, \rho_n$ or $\rho$. Moreover, since $\rho \in T_g \cap T_E_g$, we have for $i = 1, \ldots, n$, $\rho_i \in T_g \cap T_E_g$ and $\rho'' \in T_g \cap T_E_g$ and each of them has two occurrences in $U$. If we consider $\rho$ as an element of $T_E_g$ (respectively $T_g$), $\rho_1, \ldots, \rho_n$ are elements of $T_g$ (respectively $T_E_g$) and $\rho''$ of $T_E_g$ (respectively $T_g$). So $\rho'$ has two occurrences in $U$ such that one is element of $T_E_g$ and the other of $T_g$.

We define in figure 7 an algorithm constructing the multi-set of types that we must duplicate when we expand a type.

**Lemma 14** Let $U$ be a ground B-type and $\mu \in \mathcal{L}(U) \cap T_g$. $\text{Clos}(\mu, U)$ is well-defined and verifies the following conditions:

- $\text{Clos}(\mu, U) \subset \mathcal{L}(U) \cap T_E_g$
- $\text{Clos}(\mu, U) = \mu$ is a ground B-type
- $\text{Clos}(\mu, U)$ is the unique sub-multi-set of $\mathcal{L}(U) \cap T_E_g$ which verifies the previous condition.

**Proof** by induction on the structure of $U$.

- If $U = [\rho] \Rightarrow \rho$ then we notice that $\mu \neq \rho$, otherwise $\mu \notin \mathcal{L}(U) \cap T_g$. By the lemma 13, we know that every sub-term of $\rho$ has two occurrences, one belonging to $T_E_g$ and the other belonging to
\[ Clos(\mu, U) = \]

- Case \( U = [\rho] \Rightarrow \rho \)
  return \([\rho]\)  

- Case \( U = [\nu_1, \ldots, \nu_n] \Rightarrow \alpha \)
  let \( i \in \{1, \ldots, n\} \) such that \( \nu_i = [\mu_1^1, \ldots, \mu_1^{n_1}] \rightarrow \cdots \rightarrow [\mu_p^1, \ldots, \mu_p^{n_p}] \Rightarrow \alpha \)  
  (\( E_j^k \))_{j=1,\ldots,p; k=1,\ldots,n_j} \) the partition of \([\nu_1, \ldots, \nu_i-1, \nu_{i+1}, \ldots, \nu_n]\)  
  such that \( \forall j \in \{1, \ldots, p\}, \forall k \in \{1, \ldots, n_j\}, E_j^k \Rightarrow \mu_j^k \) is a ground B-type  
  if \( \exists j, k \) such that \( \mu = \mu_j^k \)  
  then return \( E_j^k \)  
  else if \( \exists j, k \) such that \( \mu \in \mathcal{L}(E_j^k \Rightarrow \mu_j^k) \cap T_{E_g} \)  
  then return \( Clos(\mu, E_j^k \Rightarrow \mu_j^k) \)  
  else fail  

- Case \( U = [\nu_1, \ldots, \nu_n] \Rightarrow [\nu_{n+1}, \ldots, \nu_{n+m}] \Rightarrow \mu' \)  
  return \( Clos(\mu, [\nu_1, \ldots, \nu_{n+m}] \Rightarrow \mu') \)

Figure 7: Closure algorithm

\( T_g \). Thus, there exists an occurrence of \( \mu \) in \( U \) which belongs to \( \mathcal{L}(U) \cap T_{E_g} \). Moreover \([\mu] \Rightarrow \mu \) is a ground B-type since \( \mu \in T_{E_g} \cap T_g \) and \([\mu] \) is the unique sub-multi-set of \( \mathcal{L}(U) \cap T_{E_g} \) since \( \mu \) as only two occurrences in \( U \).

- If \( U = [\nu_1, \ldots, \nu_n] \Rightarrow \alpha \) then we distinguish several cases:
  
  - if \( \exists(j, k)/\mu = \mu_j^k \), then by definition of a ground B-type \( E_j^k \) is well defined and unique. Moreover, \( E_j^k \subset \mathcal{L}(U) \cap T_{E_g} \) and \( E_j^k \Rightarrow \mu \) is a ground B-type.
  
  - if \( \exists(j, k)/\mu \in \mathcal{L}(E_j^k \Rightarrow \mu_j^k) \cap T_{E_g} \) then by the induction hypothesis on \( E_j^k \Rightarrow \mu_j^k \), \( Clos(\mu, E_j^k \Rightarrow \mu_j^k) \) is well defined and verifies the conditions of the lemma. Since \( \mathcal{L}(E_j^k \Rightarrow \mu_j^k) \subset \mathcal{L}(U) \), we only must show that \( Clos(\mu, E_j^k \Rightarrow \mu_j^k) \) is the unique sub-multi-set of \( \mathcal{L}(U) \cap T_{E_g} \). Since each \( E_j^k \Rightarrow \mu_j^k \) is a ground B-type, therefore closed, they are disjoint from each other and we deduce the unicity.

  - otherwise it is impossible since we suppose that \( \mu \in \mathcal{L}(U) \cap T_g \).

- If \( U = [\nu_1, \ldots, \nu_n] \Rightarrow [\nu_{n+1}, \ldots, \nu_{n+m}] \Rightarrow \mu' \) then the induction hypothesis gives the result.\( \square \)

The next definition is just a syntactic facility.

**Definition** Let \( U \) be a ground B-type and \( \mu \in \mathcal{L}(U) \cap T_g \) a type, the ground B-type \( Clos(\mu, U) \Rightarrow \mu \) is called the closure of \( \mu \) in \( U \).

An expansion makes a number of copies of several types. We want each copy of a type to be disjoint from all others, i.e. two copies of the same type have no common type variables. In order to be precise, we define specific substitutions which will make the copies of types exactly as we need.

**Definition** Let \( S \) be a substitution, we say that \( S \) is a renaming substitution if for all \( \alpha \in \text{Dom}(S) \), \( S(\alpha) = \beta \) where \( \beta \) is a type variable and \( S \) is injective. Furthermore, if \( \text{Range}(S) \) is a set of new
type variables, we say that $S$ is a fresh renaming substitution. Thus any renaming substitution $S$ has an inverse, written $S^{-1}$ which is also a renaming substitution, but even if $S$ is a fresh renaming substitution, $S^{-1}$ is not a fresh renaming substitution since type variables in $\operatorname{Range}(S^{-1}) = \operatorname{Dom}(S)$ are not fresh.

We can now give the definition of expansions.

**Definition** Let $p$ be an integer. For all types $\mu$ in $T_g$ we define an operation of expansion of $\mu$, on the ground B-type $U$, written $E(p, \mu)$ by:

$$E(p, \mu)(U) = \begin{cases} U & \text{if } \mu \notin \mathcal{L}(U) \\ U' & \text{otherwise} \end{cases}$$

where if $R_1, \ldots, R_p$ are $p$ fresh renaming substitutions of domain $\operatorname{TypeVar}(Clos(\mu, U))$, $U'$ is obtained from $U$ by replacing each occurrence of an element $\nu$ of $Clos(\mu, U)$ by $R_1(\nu), \ldots, R_p(\nu)$ and $\mu$ by $R_1(\mu), \ldots, R_p(\mu)$. We remark that since the renaming substitutions $R_1, \ldots, R_p$ are not unique, the expansion of $\mu$ in $U$ is defined up to a renaming.

Since our work is essentially based on the structure of types, we want to prove that expansions do not change this structure. So we prove that the set of ground pairs is closed under expansion.

**Definition** We say that two types $\rho_1$ et $\rho_2$ have the same structure in one of the following cases:

- if $\rho_1 = \alpha$ and $\rho_2 = \beta$
- if $\rho_1 = [\mu_1, \ldots, \mu_n] \rightarrow \nu$, $\rho_2 = [\mu'_1, \ldots, \mu'_m] \rightarrow \nu'$ and for all $j \in \{1, \ldots, m\}$, there exists $i_j \in \{1, \ldots, n\}$ such that $\mu_{i_j}$ and $\mu_j$ have the same structure, and if $\nu$ and $\nu'$ have the same structure.
- if $\rho_1$ and $\rho_2$ belong to $T_g$ and are such that $\rho_1 = [\nu_1, \ldots, \nu_n] \rightarrow \mu$ and $\rho_2 = [\nu'_1, \ldots, \nu'_n] \rightarrow \mu'$ for all $i \in \{1, \ldots, n\}$, $\nu_i$ and $\nu'_i$ have the same structure and $\mu$ and $\mu'$ have the same structure.

**Remark:** Let $\rho$ be a type, $\mu \in T_g \cap \mathcal{L}(\rho)$ and $p$ an integer. If we replace in $\rho$ the occurrence of $\mu$ by $R_1(\mu), \ldots, R_p(\mu)$ to obtain $\rho'$, where $R_1, \ldots, R_p$ are fresh renaming substitutions then $\rho'$ have the same structure as $\rho$. The proof by induction on the structure of $\rho$ is immediate.

As usual, we extend the notion of having the same structure to B-types without difficulty. We say that two B-types $U_1$ and $U_2$ have the same structure if one of the following cases is verified:

- $U_1 = [\rho_1] \Rightarrow \rho_1, U_2 = [\rho_2] \Rightarrow \rho_2$ and $\rho_1$ and $\rho_2$ have the same structure.
- $U_1 = [\nu_1, \ldots, \nu_n] \Rightarrow \alpha$, $U_2 = [\nu'_1, \ldots, \nu'_n] \Rightarrow \beta$ and for all $j \in \{1, \ldots, m\}$, there exists $i_j \in \{1, \ldots, n\}$ such that $\nu_{i_j}$ and $\nu'_j$ have the same structure.
- $U_1 = [\nu_1, \ldots, \nu_n] \Rightarrow [\nu_{n+1}, \ldots, \nu_{n+p}] \rightarrow \mu$, $U_2 = [\nu'_1, \ldots, \nu'_m] \Rightarrow [\nu'_{m+1}, \ldots, \nu'_{m+p}] \rightarrow \mu'$, $\mu$ and $\mu'$ have the same structure. For all $j \in \{1, \ldots, m\}$ (respectively $\{m+1, \ldots, m+p\}$), there exists $i_j \in \{1, \ldots, n\}$ (respectively $\{n+1, \ldots, n+p\}$) such that $\nu_{i_j}$ and $\nu'_{i_j}$ have the same structure.
Lemma 15 Let $U$ be a ground $B$-type, $\mu' \in T_g$, and $p$ an integer. Then $E_{(p,\mu')}(U)$ is a ground $B$-type which has the same structure as $U$.

Proof first by cases on $\mu'$ then by induction on the structure of $U$.

- If $\mu' \notin \mathcal{L}(U)$ then $E_{(p,\mu')}(U) = U$ is a ground $B$-type which has the same structure as $U$.

- Otherwise we reason by induction on the structure of $U$ and three cases can arise:

  o if $U = [\rho] \Rightarrow \rho$ then $\mu'$ is a sub-term of $\rho$ and
    $\text{Clos}(\mu', U) = [\mu']$. So we have $E_{(p,\mu')}(U) = [\rho] \Rightarrow \rho'$ where we have replaced $\mu'$ in $\rho$ by the $p$ copies of $\mu'$: $R_1(\mu'), \ldots R_p(\mu')$, to obtain $\rho'$. Thus according to the previous remark, $\mu$ and $\mu'$ have the same structure. We can deduce that $U$ and $E_{(p,\mu')}(U)$ have also the same structure.

  o if $U = [\nu_1, \ldots, \nu_n] \Rightarrow \alpha$ then since $U$ is a ground $B$-type, there exists $i \in \{1, \ldots, n\}$ such that $\nu_i = [\nu_1^1, \ldots, \nu_1^{n_i}] \rightarrow \cdots \rightarrow [\nu_m^1, \ldots, \nu_m^{n_m}] \Rightarrow \alpha$ and there exists a partition $(E_j^k)_{j=1 \ldots m, k=1 \ldots n_j}$ of $[\nu_1, \ldots, \nu_1, \ldots, \nu_n]$ such that for all $j \in \{1, \ldots, m\}$ and all $k \in \{1, \ldots, n_j\}$, $E_j^k \Rightarrow \mu_j^k$ is a ground $B$-type.

    if there exist $j$ and $k$ such that $\mu' = \mu_j^k$ then $\text{Clos}(\mu', U) = E_j^k$ and so by definition of an expansion, we have:
    \[ E_{(p,\mu')}(U) = E_j^k \]
    where for all $l \in \{1, \ldots, p\}$, $E_j^k \Rightarrow \mu_j^k$ is a ground $B$-type and a renaming substitution does not change the structure of a $B$-type. We deduce that $E_{(p,\mu')}(U)$ is a ground $B$-type which has the same structure as $U$.

    - otherwise there exist $j$ and $k$ such that $\mu' \in \mathcal{L}(E_j^k \Rightarrow \mu_j^k) \cap T_g$. We write $U_j^k = E_j^k \Rightarrow \mu_j^k$. Since $U_j^k$ is a ground $B$-type, we can apply the expansion $E_{(p,\mu')}$.
      \[ E_{(p,\mu')}(U) = \]
      \[ \text{which is a ground $B$-type with the same structure as } U. \]

  o if $U = [\nu_1, \ldots, \nu_n] \Rightarrow [\nu_{n+1}, \ldots, \nu_{n+m}] \Rightarrow \mu$ then we write $U' = [\nu_1, \ldots, \nu_{n+m}] \Rightarrow \mu$.

By definition of a ground $B$-type, $U'$ is immediately a ground $B$-type. So we can apply the expansion $E_{(p,\mu')}(U')$. By induction, the result of this application is a ground $B$-type with the same structure as $U'$.

Thus $E_{(p,\mu')}(U') = [\nu_1, \ldots, \nu_q] \Rightarrow \mu'$ where $\mu$ and $\mu'$ have the same structure and for all $j \in \{1, \ldots, q\}$, there exists $i_j \in \{1, \ldots, n + m\}$ such that $\nu_{i_j}$ and $\nu_j$ have the same structure.
Let \( \nu'_j, \ldots, \nu'_{j_1} \) and \( \nu'_{j_2+1}, \ldots, \nu'_{j_q} \) be the two sub-multi-sets of \( \nu'_1, \ldots, \nu'_q \) constituted by the types with the same structure as the types of the multi-set \( \nu_1, \ldots, \nu_n \) and \( \nu_{n+1}, \ldots, \nu_{n+m} \) respectively. Then \( E(p, \nu')(U) = [\nu'_1, \ldots, \nu'_{j_q}] \mapsto \mu' \) and \( E(p, \nu')(U) \) is a ground B-type with the same structure as \( U \).

\( \Box \)

The next lemma specifies some results about expansions' behavior according to the structure of B-types to which they are applied.

**Lemma 16** Let \( E \) be an expansion.

- If \( E(\overline{A} \Rightarrow \mu) = \overline{A'} \Rightarrow \mu' \), then \( E(\overline{A} \setminus \{x\} \Rightarrow A(x) \Rightarrow \mu) = \overline{A'} \setminus \{x\} \Rightarrow \mu' \)

- If for \( i = 1, \ldots, n, \ E(E_i \Rightarrow \mu_i) = E'_i \Rightarrow \mu'_i \), then \( E(E_1 + \cdots + E_n + [\mu_1] \Rightarrow \cdots \Rightarrow [\mu_n] \Rightarrow \alpha) \Rightarrow \alpha = E'_1 + \cdots + E'_n + [\mu'_1] \Rightarrow \cdots \Rightarrow [\mu'_n] \Rightarrow \alpha \Rightarrow \alpha \)

**Proof** By definition of expansion and application of lemma 15.\( \Box \)

## 8 Principal typing of normalizable \( \lambda \)-terms

This section states the existence of principal types for all normalizable \( \lambda \)-terms. This result is not new, since it can be found in [6, 26, 35]. The authors of these papers introduce a notion of approximants, also named \( \lambda \Omega \)-normal forms, and define principal typing for these extended normal forms before generalizing to \( \lambda \)-terms using an approximation property, i.e. \( B \vdash e : \mu \) if and only if there exists an approximant \( a \) of \( e \) such that \( B \vdash a : \mu \). Here we are only interested in normalizable \( \lambda \)-terms. Thus, thanks to theorem 3, it is enough to use normal forms. We do not need to introduce approximants which significantly simplifies the proofs.

The substitution and expansion operations are both necessary to find a possible pair for a normal form from its principal pair. However these operations must be applied in an appropriate order.

**Definition** We name chain a composition of substitutions, expansions and renaming substitutions, of the form \( S_n \circ \cdots \circ S_1 \circ O_{n+1} \circ \cdots \circ O_1 \) where \( S_i \) is a substitution for \( i = 1, \ldots, n \) and \( O_j \) is either a renaming substitution or an expansion for \( j = 1, \ldots, m \).

From now on, we will not need to distinguish the different \( S_i \) (respectively \( O_j \)) from each other. So it will be enough to write a chain \( C \) simply by \( C \circ O \) where \( C \) will be a composition of substitutions and \( O \) a composition of renaming substitutions and expansions.

**Theorem 12** Let \( N \) be a term in normal form such that \( \vdash_{sw} N : \mu; A \). If \( \text{Infer}(N) = (\mu_p, A_p) \) then there exists a chain \( C \) such that \( C(\overline{A_p} \Rightarrow \mu_p) = \overline{A} \Rightarrow \mu \).

**Proof** by induction on the structure of \( N \).

- If \( N = x \) then we have derived \( \vdash_{sw} x : \mu; \{x : \mu\} \) and \( \text{Infer}(N) = (\alpha, \{x : \alpha\}) \) where \( \alpha \) is fresh type variable. If we define \( C \) by \( C = [\alpha / \mu] \), we have \( C([\alpha] \Rightarrow \alpha) = [\mu] \Rightarrow \mu \).

- If \( N = \lambda x. N_1 \) then we have derived:

\[
\begin{align*}
\vdash_{sw} N_1 : \mu_1; A_1 \\
\vdash_{sw} \lambda x. N_1 : A_1(x) \Rightarrow \mu_1; A_1 \setminus \{x\}
\end{align*}
\]

32
with $\mu = A_1(x) \rightarrow \mu_1$ and $A = A_1 \setminus \{x\}$.

On the other hand, if $\text{Infer}(N_1) = (\mu_1 p \, A_1 p)$ then $\text{Infer}(\lambda x. N_1) = (A_1 p(x) \rightarrow \mu_1 p, A_1 p \setminus \{x\})$ with $\mu_p = A_1 p(x) \rightarrow \mu_1 p$ and $A_p = A_1 p \setminus \{x\}$.

By the induction hypothesis, there exists a chain $C$ such that $C(A_1 p \Rightarrow \mu p) = A_1 \Rightarrow \mu_1$. Moreover, $A_1 p = A_1 p \setminus \{x\} \cup A_1 p(x)$ and a chain respects the structure of B-types. So we have:

$$C(A_1 p \setminus \{x\} \Rightarrow A_1 p(x) \rightarrow \mu_1 p) = A_1 \setminus \{x\} \Rightarrow A_1(x) \rightarrow \mu_1$$

i.e., $C(A_p \Rightarrow \mu p) = A \Rightarrow \mu$.

- If $N = x \, N_1 \ldots N_n$ then we have derived:

$$\frac{\vdash_{s\omega} x : \mu_1 ; A \vdash_{s\omega} N_1 : \mu_2 ; A_1^1} {\vdash_{s\omega} x \, N_1 \ldots N_n : \mu_2 ; B_1}$$

where $\mu_k = [\mu_1^k, \ldots, \mu_n^k] \rightarrow \ldots \rightarrow [\mu_1, \ldots, \mu_n] \rightarrow \mu$, $A = \{x \in [[\mu_1^1, \ldots, \mu_1^m]] \rightarrow \ldots \rightarrow [\mu_n^1, \ldots, \mu_n^m] \rightarrow \mu\}$ and for $k = 1, \ldots, n$, $B_k = A + A_1^1 + \cdots + A_1^m + \cdots + A_n^m$.

On the other hand, if $\alpha$ is a fresh type variable and if for $i = 1, \ldots, n$, $\text{Infer}(N_i) = (\mu_i p, A_i p)$, then

$$\text{Infer}(x \, N_1 \ldots N_n) = (\alpha, A_p + A_1 p + \cdots + A_n p)$$

where $A_p = \{x \in [[\mu_1 p] \rightarrow \cdots \rightarrow [\mu_n p] \rightarrow \alpha]\}$.

Moreover, from the induction hypothesis, we deduce that for all $i \in \{1, \ldots, n\}$, there exist $m_i$ chains $C_i^1, \ldots, C_i^m_i$ such that $\forall j \in \{1, \ldots, m_i\}, C_i^j(A_1 p \Rightarrow \mu_i p) = A_i^j \Rightarrow \mu_i^j$.

We write for all $i \in \{1, \ldots, n\}$ and all $j \in \{1, \ldots, m_i\}$, $C_i^j = S_i^j \circ O_i^j$ where $S_i^j$ names a composition of substitutions and $O_i^j$ a composition of expansions and renaming substitutions and $A_i^j \Rightarrow \mu_i^j = O_i^j(A_1 p \Rightarrow \mu_i p)$.

Let $E_{(m, \mu p)}$ be an expansion for all $i \in \{1, \ldots, n\}$ and $R_i^1, \ldots, R_i^m$ the associated renaming substitutions. If we define the chain $C$ by:

$$C = [\alpha/\mu] \circ S_{(m_1)}^m \circ \cdots \circ S_{(m_2)}^m \circ \cdots \circ S_{(m_1)}^1 \circ O_{(m_1)}^m \circ (R_{(m_1)}^m)^{-1} \circ \cdots \circ O_{(m_1)}^1 \circ (R_{(m_1)}^1)^{-1} \circ E_{(m_1, \mu p)} \circ \cdots \circ E_{(m_1, \mu p)}$$

then $C(A_p + A_1 p + \cdots + A_n p \Rightarrow \alpha) = B_n \Rightarrow \mu$.

In fact, we have:

$$U' = E_{(m_1, \mu p)} \circ \cdots \circ E_{(m_1, \mu p)}(A_p + A_1 p + \cdots + A_n p \Rightarrow \alpha) = [R_{(m_1)}^1(\mu_1 p), \ldots, R_{(m_1)}^1(\mu_1 p)] \rightarrow \cdots \rightarrow [R_{(m_n)}^1(\mu_n p), \ldots, R_{(m_n)}^1(\mu_n p)] \rightarrow \alpha + R_{(m_1)}^1(A_1 p) + \cdots + R_{(m_1)}^1(A_1 p) + \cdots + R_{(m_n)}^1(A_1 p) + \cdots + R_{(m_n)}^1(A_1 p) \Rightarrow \alpha$$
Then for all \(i \in \{1, \ldots, n\}\) and all \(j \in \{1, \ldots, m_i\}\), \(O_i^{m_i} \circ (P_{n_{m_i}}^{m_i})^{-1} \circ \ldots \circ O_i^{1} \circ (P_{n_{m_i}}^{1})^{-1} \circ \ldots \circ O_i^{m_1} \circ (R_i^{m_1})^{-1} \circ \ldots \circ O_i^{1} \circ (R_i^{1})^{-1}(U) = A_i^j \Rightarrow \mu_i^j\), so we have:

\[
U'' = O_n^{m_n} \circ (P_n^{m_n})^{-1} \circ \ldots \circ O_1^{m_1} \circ (P_1^{m_1})^{-1} \circ \ldots \circ O_1^{1} \circ (P_1^{1})^{-1} \circ O_1^{m_1} \circ (R_1^{m_1})^{-1} \circ \ldots \circ O_1^{1} \circ (R_1^{1})^{-1}(U') = 
[[\mu_1^1, \ldots, \mu_1^{m_1}] \rightarrow \cdots \rightarrow [\mu_n^1, \ldots, \mu_n^{m_n}] \rightarrow \alpha] + A_1 + \cdots + A_{m_1} + \cdots + A_1 + \cdots + A_{m_n} \Rightarrow \alpha
\]

and since for all \(i \in \{1, \ldots, n\}\) and all \(j \in \{1, \ldots, m_i\}\), \(S_i^j(\mu_i^j) = \mu_i^j\) and \(S_i^j(A_i^j) = A_i^j\), we have:

\[
U''' = S_n^{m_n} \circ \ldots \circ S_n^1 \circ \ldots \circ S_1^{m_1} \circ \ldots \circ S_1^1(U'') = 
[[\mu_1^1, \ldots, \mu_1^{m_1}] \rightarrow \cdots \rightarrow [\mu_n^1, \ldots, \mu_n^{m_n}] \rightarrow \alpha] + A_1 + \cdots + A_{m_1} + \cdots + A_1 + \cdots + A_{m_n} \Rightarrow \alpha
\]

and finally

\[
[\alpha/\mu](U''') = 
[[\mu_1^1, \ldots, \mu_1^{m_1}] \rightarrow \cdots \rightarrow [\mu_n^1, \ldots, \mu_n^{m_n}] \rightarrow \mu] + A_1 + \cdots + A_{m_1} + \cdots + A_1 + \cdots + A_{m_n} \Rightarrow \mu
\]

So \([\alpha/\mu](U''') = \overline{A_n} \Rightarrow \mu\). □

**Corollary** Let \(e\) be a normalizable term such that \(\vdash_{\omega} e : \mu ; A\), \(N\) its normal form and \((\mu_p, A_p) = \text{Infer}(N)\). Then there exists a chain \(C\) such that \(C(\overline{A_p} \Rightarrow \mu) = \overline{A} \Rightarrow \mu\).

**Proof**

Since \(e = \beta N\) by theorem 3 we have \(\vdash_{\omega} N : \mu ; A\) and we deduce the result directly from theorem 12. □

In other words, there exists a principal type for all normalizable \(\lambda\)-terms.

### 9 Related work

The first work on intersection type discipline has more than fifteen years. Since then many authors have been interested in intersection types or used them. But the presentation of this discipline does not really change since the beginning.

In [27, 5], M. Coppo, M. Dezani-Ciancaglini and P. Sallé introduce first a notion of intersection types which allows terms and term variables to have more than one type. In [3], M. Coppo and M. Dezani-Ciancaglini give the bases of an intersection type system and provide the first study of properties of a such system, but the system presented in [1] is considered as the reference in intersection type discipline and is the most often used and studied. According to J. L. Krivine in [13] (we use here his notations), there are essentially three intersection type systems. Types are formed with the constructors \(\rightarrow\) and \(\wedge\) for system \(D\) [3], a universal type \(\omega\) for the system \(D_{\omega}\) [7], and a partial order \(\leq\) on types for the system \(D_{\omega, \leq}\) [1].

The theoretical study of system \(D\) led to results about \(\lambda\)-calculus and to the following characterization: a term is strongly normalizable if and only if it is typable in system \(D\) [22, 15]. In system \(D_{\omega}\) a term is normalizable if and only if it is typable in system \(D_{\omega}\) with a type in which \(\omega\) does not occur [7, 15, 13]. The system \(D_{\omega, \leq}\) gives rise to a filter lambda model that has been used as a starting point for much other work (see for example [4, 8, 9, 12]) and which is semantically
complete [1]. Some papers about the principal type property complete these theoretical studies [6, 26, 35]. There are also many works which use intersection types in several domains (programming languages, partial evaluation, term rewriting system). [20, 10, 23, 11, 31, 34, 14] is a non exhaustive list of these works.

In [32, 33], S. van Bakel determines the essential characteristics of the intersection type systems and proposes two restrictions of system $\mathcal{D}_{\omega<}$ which have the same properties as the original system. As far as we know, his work is the first real advance in the simplification of the presentation of the intersection type discipline since the initial presentations.

Our result about the equivalence between normal forms and principal types has been reported in [28] as a preliminary report.

## 10 Conclusion

In this paper we have introduced a restriction of system $\mathcal{D}$ in the sense that intersections only occur on the left hand side of an arrow and are not types. This restriction corresponds to strict types defined by S. van Bakel in [32, 35]. But in the strict type system, S. van Bakel defines a partial order on types and his approach of the principal type property is close to the one proposed in the other works. In this article, we study principal types through their structural properties.

First, we have proved that though we have restricted the set of types in our intersection type system, this expressiveness is the same as the classical intersection type systems. We characterize by typing the same sets of types i.e., normalizable and head normalizable $\lambda$-terms.

Then, with a restriction on the structure of types that occur in the inference rule for variables we prove the principal type property for normal forms in the classical sense.

We then have completely characterized the structure and the properties of principal types inferred for normal forms thanks to an algorithm for reconstructing normal forms from principal pairs of types and constraint environments.

According to the structure of principal types, we define ground types which correspond to S. van Bakel’s ground types. But, as we did for principal types, we have studied in detail the structure of these ground types. These structural properties lead us to a simple definition of the expansion operation. Then we prove that in our intersection type system, expansions and substitutions are enough to find all possible types of a normalizable $\lambda$-term from a unique type called its principal type.

These results shed a new light on principal typing and we expect a better understanding of links between polymorphic typing and $\beta$-reduction, problem that we intend to study in future work.
